Abstract

In order to reduce the Gibbs phenomenon exhibited by the partial Fourier sums of a periodic function $f$, defined on $[-\pi, \pi]$, discontinuous at 0, Driscoll and Fornberg [1] suggested the construction of a class of approximants which incorporate the knowledge of that singularity. More precisely, their approach is the following one: let $g_2$ denote the series such that $f(t) = \Re(g_2(e^{it}))$. Then, the goal is to approach $g_2$ on the unit circle (and more precisely its real part). It is typical that the singularity of the function $f$, located at 0 say, corresponds to a logarithmic singularity for $g_2$, then located at 1, and that this function $g_2$ is analytic in the complex plane, with a branch cut that can be taken as the interval $[1, \infty)$. Defining $g_1(z) = \log(1 - z)$, we may consider the problem of determining polynomials $p_0, p_1, p_2$ such that

$$p_0(z) + p_1(z)g_1(z) + p_2(z)g_2(z) = \mathcal{O}(z^{n_0+n_1+n_2+2}) \quad (z \to 0)$$

where $n_j$ denotes the degree of $p_j$, $j = 0, 1, 2$. We can then propose the Hermite-Padé approximant

$$\Pi_2(z) = -\frac{p_0(z) + p_1(z)g_1(z)}{p_2(z)}, \quad (1)$$

to approximate $g_2$. Note that when $p_1(z) = 0$ (or formally $n_1 = -1$) we recover the usual Padé approximant of $g_2$ of type $(n_0, n_2)$.

Convincing numerical experiments have been obtained by Driscoll and Fornberg, but no error estimates have been proven so far. In this talk we obtain rates of convergence of sequences of Hermite–Padé approximants for a class of functions known as Nikishin systems. Our theoretical findings and numerical experiments confirm that particular sequences of Hermite-Padé approximants (diagonal and row sequences, as well as linear HP approximants) are more efficient than the more elementary Padé approximants, particularly around the discontinuity of the goal function $f$.
