## Purpose

## In this talk,

- we start introducing the well-known Tchakaloff theorem (and one of its variants)
existence theorem of certain algebraic and low cardinality cubature rules with positive weights on a multivariate compact domain $\Omega \subset \mathbb{R}^{d}$;
- we compress cubature rules, we show how, from cubature rules on $\Omega$ (w.r.t. a positive measure) with positive weights and interior nodes (i.e. of Pl-type), whose algebraic degree of precision $A D E$ is equal to $m$ and the number of nodes higher than the dimension " $r$ " of the polynomial space $\mathbb{P}_{m}(\Omega)$ of total degree $m$, we can extract rules of PI-type but with at most " $r$ " nodes, by means of Lawson-Hanson algorithm;
- application to Quasi-Montecarlo Cubature: rule compression given a Quasi-Montecarlo Cubature rule (acronym: QMC) and a certain degree of precision $m$, we compress the QMC rule with a positive one, that provides the same results over polynomials of degree at most $m$;
- some multivariate examples results over bivariate and trivariate domains, peculiarities of volumes and surfaces obtained by union of balls.

Important: all the Matlab routines used in this talk are available at the author's homepage.

Example: quadrature over polygons (triang. based approach)

## Paper

## Compressed cubature over polygons with applications to optical design (2020)

- purpose: cubature formula over a convex, nonconvex or even multiply connected polygons $\Omega$.
■ strategy: once a minimal triangulation of $\Omega$ is available, we obtain the rule by applying an almost-minimal rule of PI-type on each triangle with the wanted ADE, summing the contributions.

## Remark

- minimal triangulation: one can triangulate a general M-sides polygon via $M-2$ triangles (easy task in a convex polygon, not trivial for a general one),
- almost-minimal rule the number of its nodes is almost minimal between those having a certain degree of precision and requirement on the nodes (e.g. internal) and weights (e.g. positive).

Example: quadrature over polygons (triang. based approach)

Figure: Examples of polygonal domains (ADE=9).
Left: a convex domain with 6 sides ( 76 nodes), Right: a non-convex domain with 9 sides (133 nodes).
Note: all the weights are positive.

Example: quadrature over polygons (triang. based approach)

- Pros: In general these rules always have internal nodes as well as positive weights.
■ Cons: Rule still may have high cardinality if the polygon has many sides.
Observe that in the examples above for $A D E=9$
■ convex domain: the rule has 76 nodes,
■ not convex domain: the rule has 133 nodes.

## Remark

In both cases the number of nodes is higher than the dimension of the polynomial space $\mathbb{P}_{9}$ that is equal to $(9+1)(9+2) / 2=55$.
Our project is to quickly extract from the previous one, another rule of PI-type with the same degree of precision but with a number of nodes at most equal to $\operatorname{dim}\left(\mathbb{P}_{9}\right)$ (i.e. a rule compression).

## Carathéodory-Tchakaloff Subsampling

## Paper

M. Putinar, A Note on Tchakaloff's Theorem, Proc. of AMS, Vol. 125, No. 8 (1997), 2409-2414.

## Theorem (Carathéodory-Tchakaloff, see more general Putinar theorem)

## Let

$1 \mu$ be a multivariate discrete measure supported at a finite set $X=\left\{\mathbf{x}_{k}\right\}_{k=1, \ldots, N} \subset \mathbb{R}^{d}$, with correspondent positive weights $\left\{w_{k}\right\}_{k=1, \ldots, N}$,
$2 \Phi=\operatorname{span}\left(\phi_{1}, \ldots, \phi_{r}\right)$ a finite dimensional space of $d$-variate functions defined on $\Omega \supseteq X$, with $\operatorname{dim}(\Phi \mid x) \leq r$.
Then there exist a quadrature formula with nodes $T=\left\{\mathbf{t}_{k}\right\}_{k=1, \ldots, N_{c}} \subseteq X$ and positive weights $\left\{u_{k}\right\}_{k=1, \ldots, N_{c}}$, such that $N_{c} \leq \operatorname{dim}\left(\left.\Phi\right|_{X}\right)$ and

$$
\int_{\Omega} f(\mathbf{x}) d \mu:=\sum_{k=1}^{N} w_{k} f\left(\mathbf{x}_{k}\right)=\sum_{i=1}^{N_{c}} u_{i} f\left(\mathbf{t}_{i}\right):=\int_{\Omega} f(\mathbf{x}) d \mu_{C}, \text { for all }\left.f \in \Phi\right|_{X}
$$

## Example

If we have a rule of PI-type with cardinality $N$ higher than $r=\operatorname{dim}\left(\mathbb{P}_{m}(\Omega)\right)$ then we can extract one of Pl-type with cardinality $N_{c} \leq r$, having the same integration values in $\mathbb{P}_{m}(\Omega)$.

## Carathéodory-Tchakaloff Subsampling

## Paper

Compression of multivariate discrete measures and applications (2015).
Given
■ a formula of PI-type with $\mathrm{ADE}=m$, nodes $X=\left\{\mathbf{x}_{k}\right\}_{k=1, \ldots, N} \subset \mathbb{R}^{d}$ and positive weights $\left\{w_{k}\right\}_{k=1, \ldots, N}$,
■ a basis $\left\{\phi_{1}, \ldots, \phi_{r}\right\}$ of $\mathbb{P}_{m}(\Omega)$,
let
■ $V_{i, j}=\left(\phi_{j}\left(\mathbf{x}_{i}\right)\right)$ the Vandermonde matrix at the nodes,
■ $\mathbf{b}=\left(b_{j}\right)_{j=1, \ldots, r}$ where $b_{j}=\int_{\Omega} \phi_{j} d \mu=\sum_{i=1}^{N} w_{i} \phi_{j}\left(\mathbf{x}_{i}\right)$, the vector of the $\mu$ moments.
The problem mentioned above resorts into computing a nonnegative solution with at most " $r$ " nonvanishing components to the underdetermined linear system

$$
V^{\top} \mathbf{u}=\mathbf{b}
$$

## Carathéodory-Tchakaloff Subsampling

The computation of a nonnegative solution with at most $r=\operatorname{dim}\left(\mathbb{P}_{m}(\Omega)\right)$ nonvanishing components to the underdetermined linear system $V^{\top} \mathbf{u}=\mathbf{b}$ can be perfomed finding a sparse solution to the quadratic minimum problem

$$
\text { NNLS: }\left\{\begin{array}{l}
\min _{u}\left\|V^{\top} \mathbf{u}-\mathbf{b}\right\|_{2} \\
\mathbf{u} \geq 0
\end{array}\right.
$$

via Lawson-Hanson active set method for NonNegative Least Squares (NNLS).
In Matlab this can be done by means of the Matlab built-in routine lsqnonneg as well as by the more recent LHDM by Dessole, Marcuzzi and Vianello.

## Remark

- The approach mentioned above is effective for mild ADE, say on the order of $A D E=20$ for bivariate domains and $A D E=10$ for trivariate domains.
- There are also other approaches, e.g. by based on linear programming or by a different combinatorial algorithm (recursive Halving Forest), based on SVD.

## Carathéodory-Tchakaloff Subsampling

As example, we can consider the application of the technique mentioned above to extract a rule of Pl-type, for computing a similar one on the polygonal domains treated above.

## Algorithm

input: the nodes $\left\{\mathbf{x}_{k}\right\}_{k=1, \ldots, N}$, the weights $\left\{w_{k}\right\}_{k=1, \ldots, N}$ of a Pl-type rule with $N>r$ ( $r$ is the dimension of the polynomial space $\mathbb{P}_{m}$ ) and a polynomial basis $\left\{\psi_{i}\right\}_{j=1, \ldots, r}$;
1 Vandermonde matrix: compute $U=\left(\phi_{k}\left(\mathbf{x}_{i}\right)\right)$;
12 fight ill-conditioning: compute the $Q R$ factorization with column pivoting $\sqrt{W} U(:, \pi)=Q R$, where $\sqrt{W}=\operatorname{diag}\left(\left\{w_{k}\right\}\right)$ and $\pi$ is a permutation vector; this corresponds to a change of basis $\left(\phi_{1}, \ldots, \phi_{r}\right)=\left(\psi_{1}, \ldots, \psi_{r}\right) R^{-1}$, so obtaining an orthonormal basis w.r.t. the discrete measure defined by the nodes $\left\{\mathbf{x}_{k}\right\}_{k=1, \ldots, N}$ and the weights $\left\{w_{k}\right\}_{k=1, \ldots, N}$;
3 moments: evaluate the vector $\mathbf{b}=Q^{\top} \mathbf{w}$ where $\mathbf{w}_{k}=w_{k}$;
4 compute a positive sparse solution: solve $Q^{\top} \mathbf{u}=\mathbf{b}$ by Lawson-Hanson algorithm (or its alternatives).

## Carathéodory-Tchakaloff Subsampling

By this algorithm,

- adopting as basis $\left\{\psi_{j}\right\}$ the total-degree product Chebyshev basis of the smallest Cartesian rectangle $\left[a_{1}, b_{1}\right] \times\left[a_{2}, b_{2}\right]$ containing $\Omega$, with the graded lexicographical ordering,
- from the PI-rules with $\mathrm{ADE}=9$ obtained via triangulation, we get the PI-rules below with cardinality $55=\operatorname{dim}\left(\mathbb{P}_{9}\right)$.

Figure: Examples of polygonal domains ( $\mathrm{ADE}=9$ ).
Left: a convex domain with 6 sides ( 55 nodes, the previous rule had 76 nodes), Right: a non-convex domain with 9 sides ( 55 nodes, the previous rule had 133 nodes).

## Carathéodory-Tchakaloff Subsampling

## Remark (When do not apply this technique)

We observe that this approach is useful only when the initial rule of PI-type with $A D E=m$ has cardinality higher the dimension $L$ of $\mathbb{P}_{m}(\Omega)$.
Thus it is worthless in the case of classical domains as the interval, the disk, simplex, cube, sphere, where there are explicit rules of PI-type with cardinality inferior to L.

## Remark (Cputimes on the previous domains)

For mild ADE the computation of these compressed rules is fast. Running Matlab R2022a, on a computer with an Apple M1 processor and 16GB of RAM, we had average cputimes as in the table below:

| Domain | tri. rule | compress. |
| :---: | :---: | :---: |
| Convex domain | $1.1 e-3 s$ | $1.7 e-2 s$ |
| Non-convex domain | $5.2 e-3 s$ | $1.1 e-2 s$ |

Table: Average cputime for computing rules with $A D E=9$ in the previous polygonal domains.

## Application to QMC compression

This technique can be used to compress Quasi-Montecarlo cubature rules on $\Omega \subset \mathbb{R}^{d}$ obtained by set operations of compact domains $\Omega_{1}, \ldots, \Omega_{\nu} \subset \mathbb{R}^{d}$ :

■ polynomial basis: product-type Chebyshev basis in $\mathbb{P}_{m}(\Omega)$ on the bounding box $\mathcal{R}$ of the domain $\Omega$;

- mesh points: sufficiently dense low discrepancy points in the bounding box $\mathcal{R}$ (good choice for volumes) or on a suitable subdomain of $\mathcal{R}$ containing $\Omega$ (good for surfaces); notice that if the measure of the domain is not known, it must be approximated numerically in order to apply QMC;
■ in-domain routine: in domain routine on each domain $\Omega_{k}, k=1, \ldots, \nu$ followed by suitable set operations;
- moment computation: via Quasi-Montecarlo cubature.

This allows to achieve a rule with few nodes that equals the results of the QMC rule applied to polynomials in $\mathbb{P}_{m}$.

## Purpose

Retaining the approximation power of the original QMC formula (up to a quantity proportional to the best polynomial approximation error of degree $m$ to $f$, in the uniform norm on $\Omega$ ), using much fewer nodes.

## Application to QMC compression: some advantages

■ Domains: this technique can be used to compress QMC on $\Omega \subset \mathbb{R}^{d}$ obtained by set operations of compact domains $\Omega_{1}, \ldots, \Omega_{\nu} \subset \mathbb{R}^{d}$.
■ Alternatives: very often the detection of specific features (as its boundary $\partial \Omega$ or computation of the polynomial moments) may be not available or so difficult to make extremely complicated the usage of other techniques than QMC.

- In-domain routine:
- Verification of certain inequalities: for example, the unit-ball $B(0,1)$ is defined as the set

$$
B(\mathbf{0}, 1):=\left\{\mathbf{x}=(x, y, z) \in \mathbb{R}^{3} \text { such that } x^{2}+y^{2}+z^{2} \leq 1\right\} .
$$

- Specific codes: Matlab built-in inpolygon (polygonal domains), inpolyhedra (polyhedral domains), in-rs (curved polygons with boundary defined by NURBS).

## Paper

For details about in-rs see: inRS: implementing the indicator function for NURBS-shaped planar domains, Applied Mathematics Letters, Volume 130, August 2022.

## Application to QMC compression: some bivariate examples

Figure: 231 compressed QMC nodes with exactness degree $n=20$, on complex shapes arising from union (top-left), intersection (top-right) and symmetric difference (bottom) of two NURBS-shaped domains (extraction from a million Halton points of domain bounding boxes, basis $\Phi$ obtained by orthonormalization of a tensorial type basis in the bounding box $\mathcal{R}$ of the domain $\Omega$ ).

- Domains: $\mathcal{R}$ is the smaller rectangle (with sides parallel to the axes) containing $\Omega$;
- polynomial basis: subset of tensorial-type Chebyshev basis defining $\mathbb{P}_{m}$ on $\mathcal{R}$;

■ In-domain routine: in-rs;

## Application to QMC compression: union of balls (volumes and surfaces)

Let $B\left(C_{j}, r_{j}\right)$ be a ball with center $C_{j} \in \mathbb{R}^{3}$ and radius $r_{j}>0$ and consider domains of the forms
$1 \Omega_{V}=\cup_{j=1}^{L} B\left(C_{j}, r_{j}\right)$ (volume);
2 $\Omega_{S}=\partial \cup_{j=1}^{L} B\left(C_{j}, r_{j}\right)$ (surface).

Figure: Left: union of 3 balls, Right: union of 100 balls.

## Application to QMC compression: union of balls (volumes and surfaces)

## Main difficulties:

■ their geometry can be very complicated, since the balls may intersect, even creating cavities: hard to subdivide in manageable subregions;

- depending on the balls, the polynomial space $\mathbb{P}_{m}\left(\Omega_{S}\right)$ over the surface $\Omega_{S}$ may have a dimension inferior than $\mathbb{P}_{m}\left(\mathbb{R}^{3}\right)$ (spheres are algebraic surfaces), and it is not straightforward to determine exactly a well-conditioned basis (even the computation of $\operatorname{dim}\left(\mathbb{P}_{m}\left(\Omega_{S}\right)\right)$ may be a tough problem).
Where they arise:
- molecular modelling, computational geometry, computational optics, wireless network analysis;

## Problems:

■ basic (but not trivial): exact computation of areas or volumes of such sets;

- more difficult: computing volume or surface integrals there by quadrature formulas.

## Paper

Qbubble: a numerical code for compressed QMC volume and surface integration on union of balls, submitted.

## Application to QMC compression: union of balls (volumes)

## Purpose

We intend to compress a rule, matching the QMC values of integrands in $\mathbb{P}_{m}$, in the case of the volumes, i.e. $\Omega_{v}=\cup_{j=1}^{L} B\left(C_{i}, r_{j}\right)$.

■ full QMC rule: easy,

- low discrepancy sequences in the bounding box $\mathcal{R}$ are available, and the restriction on $\Omega_{V}$ provides low discrepancy sequences;
- easy approximation of domain volume via QMC and volume of the parallelepiped $\mathcal{R}$ (bounding box);
- polynomial basis: technical and new, starting from product Chebyshev basis a trick is used to reduce computations for determining a well-conditioned basis (using just a small subset of QMC nodes);
- moment evaluation: easy, via the full QMC rule;
- compressed QMC: technical and new, a trick is used to reduce computations (again using just a small subset of QMC nodes);

## Application to QMC compression: union of balls (surfaces)

## Purpose

We intend to compress a rule, matching the $Q M C$ values of integrands in $\mathbb{P}_{m}$, in the case of the surfaces, i.e.. $\Omega_{S}=\partial \cup_{j=1}^{L} B\left(C_{j}, r_{j}\right)$ :

- full QMC rule: quite easy,

■ low discrepancy sequences $X_{j}$ in each sphere $S_{j}=\partial B\left(C_{j}, r_{j}\right)$ are available, hence one can determine after some technicalities low discrepancy sequences over $\Omega_{S}$;
■ easy approx. of $\Omega_{S}$ area via QMC and area of each sphere $S_{j}, j=1, \ldots, L$;

- polynomial basis: very technical and new,

■ usage of Matlab numerical rank revealing algorithms to determine the dimension of the polynomial space anda well-conditioned basis (the dimensions of $\mathbb{P}_{m}\left(\Omega_{s}\right)$ and $\mathbb{P}_{m}\left(\mathbb{R}^{3}\right)$ may be different);

- starting from product Chebyshev basis a trick is used to reduce computations for determining a well-conditioned basis (using just a small subset of QMC nodes);
- moment evaluation: easy,
via the full QMC rule;
- compressed QMC: technical and new,
a trick is used to reduce computations (again using a small subset of QMC nodes);

## Application to QMC compression: union of 3 balls (example on a volume)

| deg | 3 | 6 | 9 | 12 |

Table: Compression of surface QMC integration on the union 100 balls, starting from 60000 low-discrepancy points on each sphere. Compressed codes used the acronym CQMC.

## Remark

New codes are from 9.3 to 16.7 times faster than the old ones.

## Application to QMC compression: on the numerical integration of some functions

Next we show the integration errors on three test functions with different regularity, namely

- $f_{1}(P)=\left|P-P_{0}\right|^{5}$ (class $C^{4}$ with discontinuous fifth derivatives);
- $f_{2}(P)=\cos (x+y+z)$ (analytic);

■ $f_{3}(P)=\exp \left(-\left|P-P_{0}\right|^{2}\right)$ (analytic);
where $P_{0}=(0,0,0) \in \Omega$.

## Remark

- It is easy to see that for every $f \in C(\Omega)$, the following error estimate holds

$$
\left|I_{\text {СоMС }}(f)-I(f)\right| \leq \mathcal{E}_{\text {QMC }}(f)+2 \mu(\Omega) E_{n}(f ; \Omega),
$$

where $\mathcal{E}_{\text {Qмс }}(f)=\left|I_{\text {Qмс }}(f)-I(f)\right|$ and $E_{n}(f ; \Omega)$ is the best approximation error of $f$ w.r.t. $\mathbb{P}_{n}$, in $\Omega$, w.r.t. the sup-norm.

- The reference values of the integrals have been computed by a QMC formula starting from $10^{8}$ Halton points in the bounding box.

Application to QMC compression: on the numerical integration of some functions, 3 balls volumes

| deg | 3 | 6 | 9 | 12 |
| :---: | :---: | :---: | :---: | :---: |
| $E^{\text {QMC }}\left(f_{1}\right)$ | $1.1 \mathrm{e}-04$ |  |  |  |
| $E^{\text {new }}\left(f_{1}\right)$ | $7.7 \mathrm{e}-03$ | $8.9 \mathrm{e}-05$ | $1.1 \mathrm{e}-04$ | $1.1 \mathrm{e}-04$ |
| $E^{Q M C}\left(f_{2}\right)$ | $1.7 \mathrm{e}-04$ |  |  |  |
| $E^{\text {new }}\left(f_{2}\right)$ | $4.5 \mathrm{e}-03$ | $6.5 \mathrm{e}-05$ | $1.7 \mathrm{e}-04$ | $1.7 \mathrm{e}-04$ |
| $E^{\text {QMC }}\left(f_{3}\right)$ | $2.2 \mathrm{e}-04$ |  |  |  |
| $E^{\text {new }}\left(f_{3}\right)$ | $2.4 \mathrm{e}-02$ | $1.4 \mathrm{e}-02$ | $3.5 \mathrm{e}-05$ | $2.2 \mathrm{e}-04$ |

Table: Example with 100 balls (the reference values are computed via QMC starting from $10^{8}$ Halton points in the bounding box).

Application to QMC compression: on the numerical integration of some functions, 3 balls surfaces

| deg | 3 | 6 | 9 | 12 |
| :---: | :---: | :---: | :---: | :---: |
| $E^{Q M C}\left(f_{1}\right)$ | $3.9 \mathrm{e}-06$ |  |  |  |
| $E^{\text {new }}\left(f_{1}\right)$ | $1.1 \mathrm{e}-04$ | $6.3 \mathrm{e}-07$ | $4.0 \mathrm{e}-06$ | $3.9 \mathrm{e}-06$ |
| $E^{Q M C}\left(f_{2}\right)$ | $8.6 \mathrm{e}-05$ |  |  |  |
| $E^{\text {new }}\left(f_{2}\right)$ | $6.7 \mathrm{e}-01$ | $1.0 \mathrm{e}-02$ | $5.9 \mathrm{e}-04$ | $8.6 \mathrm{e}-05$ |
| $E^{\text {QMC }}\left(f_{3}\right)$ | $5.8 \mathrm{e}-06$ |  |  |  |
| $E^{\text {new }}\left(f_{3}\right)$ | $3.0 \mathrm{e}-01$ | $2.5 \mathrm{e}-03$ | $6.9 \mathrm{e}-04$ | $4.8-05$ |

Table: Compression of surface QMC integration on the union 3 balls (the reference values are computed via QMC starting from $10^{6}$ points on each sphere).

Application to QMC compression: on the numerical integration of some functions, 100 balls surfaces

| deg | 3 | 6 | 9 | 12 |
| :---: | :---: | :---: | :---: | :---: |
| $E^{Q M C}\left(f_{1}\right)$ | $4.0 \mathrm{e}-05$ |  |  |  |
| $E^{\text {new }}\left(f_{1}\right)$ | $2.3 \mathrm{e}-03$ | $2.9 \mathrm{e}-05$ | $4.0 \mathrm{e}-05$ | $4.0 \mathrm{e}-05$ |
| $E^{Q M C}\left(f_{2}\right)$ | $2.0 \mathrm{e}-04$ |  |  |  |
| $E^{\text {new }}\left(f_{2}\right)$ | $5.2 \mathrm{e}-01$ | $3.6 \mathrm{e}-04$ | $1.9 \mathrm{e}-04$ | $2.0 \mathrm{e}-04$ |
| $E^{\text {QMC }}\left(f_{3}\right)$ | $1.6 \mathrm{e}-04$ |  |  |  |
| $E^{\text {new }}\left(f_{3}\right)$ | $4.1 \mathrm{e}-01$ | $4.8 \mathrm{e}-03$ | $1.3 \mathrm{e}-04$ | $1.6 \mathrm{e}-04$ |

Table: Compression of surface QMC integration on the union 100 balls (the reference values are computed via QMC starting from $10^{6}$ points on each sphere).
