59th Annual Meeting of the Australian Mathematical Society
Flinders University, Adelaide, South Australia
28th September - 1st October, 2015
What are Mean Field Games?
- a static game with many players
- a heuristic derivation of the MFG partial differential equations
- MFG as models of large populations of agents

Models of segregation
[joint work with Yves Achdou (Paris) and Marco Cirant (Milano)]
- Schelling’s model of urban settlements
- Mean-Field Games with two populations
- Qualitative properties: segregation?
- Numerical experiments

Ingredients:
- a bit of Game Theory (Nash equilibria)
- stochastic control
- partial differential equations
1. Introduction to MFG: motivations

Want to model dynamical phenomena with
- many very similar rational agents
- subject to noise
- non-cooperative

Examples of applications:
- **Economics**
  - financial markets (price formation and dynamic equilibria, formation of volatility)
  - general economic equilibrium with rational expectations
  - environmental policy,
- **Engineering**
  - wireless power control
  - demand side management in electric power networks,
  - traffic problems
Social sciences

- crowd motion (mexican wave "la ola", pedestrian dynamics, congestion phenomena,...)
- opinion dynamics and consensus problems,
- models of population distribution (e.g., segregation).

Goals and methods:

- get macroscopic "mean field" continuum models, simpler than the discrete models for $N$ agents,
- in analogy with the Mean Field theories in
  - Statistical Physics (kinetic theory of gases, Boltzmann and Vlasov equations)
  - Quantum Mechanics and Quantum Chemistry (Hartree-Fock models...)
- mostly using Partial Differential Equations and Stochastic methods.

Numerical methods and discrete models
Games with many players

A (static) $N$-person game is defined by

- $Q = \text{a (compact) metric space}$
- $F_i : Q^N \rightarrow \mathbb{R}$ continuous, $i = 1, \ldots, N$

Goal of the $i$th player: minimise $F_i$.

Definition of Nash equilibrium: $(x_1, \ldots, x_N) \in Q^N$ such that

$$F_i(x_1, \ldots, x_N) \leq F_i(x_1, \ldots, x_{i-1}, x_i, x_{i+1}, \ldots, x_N) \quad \forall x_i \in Q, \forall i.$$ 

Existence of the equilibria is classical, but there are many and can have a complicated structure.

We’re interested in problems with $N$ large.

Question: is there a simpler macroscopic model for large populations?
Games with many players

A (static) $N$-person game is defined by

- $Q = \text{a (compact) metric space}$
- $F_i : Q^N \rightarrow \mathbb{R}$ continuous, $i = 1, \ldots, N$

Goal of the $i$th player: minimise $F_i$.

Definition of Nash equilibrium: $(\bar{x}_1, \ldots, \bar{x}_N) \in Q^N$ such that

$$F_i(\bar{x}_1, \ldots, \bar{x}_N) \leq F_i(\bar{x}_1, \ldots, \bar{x}_{i-1}, x_i, \bar{x}_{i+1}, \ldots, \bar{x}_N) \quad \forall \ x_i \in Q, \forall i.$$ 

Existence of the equilibria is classical, but there are many and can have a complicate structure.

We’re interested in problems with $N$ large.

Question: is there a simpler macroscopic model for large populations?
Indistinguishable players

Main assumption: "homogeneous population", i.e., each cost is a symmetric function of the state of the other players.

For $N$ large, symmetric functions can be approximated by functions only of the empirical measure of their variables.

Then assume, for $\mathcal{P}(Q) := \{\text{probability measures on } Q\}$

$$\exists F : Q \times \mathcal{P}(Q) \to \mathbb{R}$$

such that the cost of the $i$-th player is

$$F_i = F \left( x_i, \frac{1}{N-1} \sum_{k \neq i} \delta_{x_k} \right),$$

depending on the other players only via their empirical measure,

with $F$ continuous w.r.t. weak* convergence on $\mathcal{P}(Q)$,
Indistinguishable players

Main assumption: "homogeneous population", i.e.,
each cost is a symmetric function of the state of the other players.

For $N$ large, symmetric functions can be approximated by functions
only of the empirical measure of their variables.

Then assume, for $\mathcal{P}(Q) := \{\text{probability measures on } Q\}$

$$\exists F : Q \times \mathcal{P}(Q) \rightarrow \mathbb{R} \text{ such that the cost of the } i\text{-th player is}$$

$$F_i = F \left( x_i, \frac{1}{N-1} \sum_{k \neq i} \delta_{x_k} \right),$$

depending on the other players only via their empirical measure,

with $F$ continuous w.r.t. weak* convergence on $\mathcal{P}(Q)$,
Indistinguishable players

For $N$ large, symmetric functions can be approximated by functions only of the empirical measure of their variables.

Then assume, for $\mathcal{P}(Q) := \{\text{probability measures on } Q\}$

$$\exists F : Q \times \mathcal{P}(Q) \to \mathbb{R} \text{ such that the cost of the i-th player is}$$

$$F_i = F \left( x_i, \frac{1}{N-1} \sum_{k \neq i} \delta_{x_k} \right),$$

depending on the other players only via their empirical measure,

with $F$ continuous w.r.t. weak* convergence on $\mathcal{P}(Q)$,
The large-population limit $N \to \infty$

**Theorem [Lions, about 2006]**

If $(\bar{x}_1^N, \ldots, \bar{x}_N^N)$ is a Nash equilibrium for the $N$-person game, then

(i) \[ \frac{1}{N} \sum_{k=1}^{N} \delta_{\bar{x}_k^N} \to^* \bar{m} \quad \text{as} \quad N \to \infty, \]

up to subsequences, $\bar{m}$ solution of

\[ \forall x \in \text{supp } \bar{m} \quad F(x, \bar{m}) = \min_{y \in Q} F(y, \bar{m}). \]

(ii) \[ \int_Q (F(x, m_1) - F(x, m_2)) \, d(m_1 - m_2) > 0 \quad \forall m_1 \neq m_2, \]

i.e., $F$ increasing $\implies$ at most one solution of (1).

**N.B.** $F$ increasing means that players don’t like the crowd.
The large-population limit \( N \to \infty \)

**Theorem [Lions, about 2006]**

If \((\overline{x}^N_1, \ldots, \overline{x}^N_N)\) is a Nash equilibrium for the \(N\)-person game, then

(i) \[
\frac{1}{N} \sum_{k=1}^{N} \delta_{\overline{x}^N_k} \to^* \overline{m} \quad \text{as} \quad N \to \infty,
\]

up to subsequences, \(\overline{m}\) solution of

\[
\forall x \in \text{supp} \overline{m} \quad F(x, \overline{m}) = \min_{y \in Q} F(y, \overline{m}).
\]

(ii) \[
\int_{Q} (F(x, m_1) - F(x, m_2)) \, d(m_1 - m_2) > 0 \quad \forall m_1 \neq m_2,
\]

i.e., \(F\) increasing \(\implies\) at most one solution of (1).

**N.B.:** \(F\) increasing means that players don’t like the crowd.
A very simple example

Where do I put my towel on the beach?

$x_i \in \mathbb{R}$ is the distance of the towel of the $i-$th person from the sea.

The cost of the $i-$th player is

$$F_i(x_1, \ldots, x_N) = f(x_i) + g\left(\frac{\#\{k : |x_i - x_k| < \varepsilon\}}{(N - 1)|B_\varepsilon|}\right)$$

which becomes a function of the empirical density by choosing

$$F(x, m) = f(x) + g(m \ast 1_{B_\varepsilon} / |B_\varepsilon|).$$

Note: $f$ is minimal at the preferred position $\bar{x}$,

$g \uparrow$ means aversion to crowd ($\implies$ uniqueness in (1)),

$g \downarrow$ means that people like crowd.
An explicit solution

Letting formally $\varepsilon \to 0$ get $F(x, m) = f(x) + g(m(x))$ and the MFG equation (1) becomes

$$\text{supp } \bar{m} \subseteq \arg \min (f(x) + g(\bar{m}(x))).$$

Sometimes can be solved explicitly, e.g.,

$$F(x, m) = \frac{|x - \bar{x}|^2}{2} + \log(m(x)).$$

Must solve

if $\bar{m}(x) > 0$ \quad \begin{equation*}
\begin{aligned}
\frac{|x - \bar{x}|^2}{2} + \log(\bar{m}(x)) = \bar{\lambda} := \min F(y, \bar{m}(y))
\end{aligned}
\end{equation*}

Then \quad \bar{m}(x) = e^{\bar{\lambda}}e^{-|x-\bar{x}|^2/2} \quad \text{and } \bar{\lambda} \text{ must be such that } \int \bar{m}(x) = 1

\implies \text{the unique solution } \bar{m} \text{ is Gaussian with mean } \bar{x}.$$

Martino Bardi (University of Padua)  Mean Field Games  Adelaide, September 30, 2015  10 / 48
If the monotonicity of $F$ fails can guess from the example the non-uniqueness and singular solutions....

So far I present 1-shot or "static" MFG, but most of the theory is on dynamic games, in fact differential games.
If the monotonicity of $F$ fails can guess from the example the non-uniqueness and singular solutions....

So far I present 1-shot or "static" MFG, but most of the theory is on dynamic games, in fact differential games.
Heuristic derivation of the main equations

Basic facts from stochastic control: an agent has dynamics

\[ dX_s = \alpha_s \, ds + \sigma \, dW_s, \quad X_t = x \in \mathbb{R}^d \]

with \( W_s \) a Brownian motion, \( \alpha_s = \text{control}, \sigma > 0 \text{ volatility} \), and the finite horizon cost functional:

\[
J_T(t, x, \alpha) := E \left[ \int_t^T L(\alpha_s) + F(X_s, m_{env}) \, ds \right] + g(X_T).
\]

Here

- \( L \) is the running cost of using the control \( \alpha_s \),
- \( F : \mathbb{R}^d \times \{ \text{prob. measures} \} \rightarrow \{ \text{Lip functions} \} \)
  is the running cost of being in the state \( X_s \), depending on the distribution of the other agents in the environment \( m_{env} \),
- \( g \) is the terminal cost.
Heuristic derivation of the main equations

Basic facts from stochastic control: an agent has dynamics

\[ dX_s = \alpha_s \, ds + \sigma \, dW_s, \quad X_t = x \in \mathbb{R}^d \]

with \( W_s \) a Brownian motion, \( \alpha_s = \text{control}, \sigma > 0 \) volatility, and the finite horizon cost functional:

\[
J_T(t, x, \alpha.) := E \left[ \int_t^T L(\alpha_s) + F(X_s, m_{env}) \, ds \right] + g(X_T).
\]

Here

- \( L \) is the running cost of using the control \( \alpha_s \),
- \( F : \mathbb{R}^d \times \{ \text{prob. measures} \} \rightarrow \{ \text{Lip functions} \} \)
  is the running cost of being in the state \( X_s \), depending on the distribution of the other agents in the environment \( m_{env} \),
- \( g \) is the terminal cost.
Define the value function

\[ v(t, x) := \inf_{\alpha} J_T(t, x, \alpha). \]

Then \( v(t, x) \) solves the Hamilton-Jacobi-Bellman equation

\[
\begin{cases}
  -\frac{\partial v}{\partial t} - \nu \Delta v + H(\nabla v) = F(x, m_{env}) & \text{in } (0, T) \times \mathbb{R}^d \\
  v(T, x) = g(x)
\end{cases}
\]

where \( \nu := \sigma^2/2, \ \Delta := \Delta_x, \ \nabla := \nabla_x \), and \( H \) is the Hamiltonian associated to \( L \):

\[ H(p) := \sup_{\alpha \in \mathbb{R}^d} \{ p \cdot \alpha - L(\alpha) \} \]

Moreover the feedback control

\[ \hat{\alpha}(t, x) = -\nabla H(\nabla v(t, x)) \]

is optimal.
Define the value function

\[ v(t, x) := \inf_{\alpha} J_T(t, x, \alpha). \]

Then \( v(t, x) \) solves the **Hamilton-Jacobi-Bellman equation**

\[
\begin{cases}
- \frac{\partial v}{\partial t} - \nu \Delta v + H(\nabla v) = F(x, m_{\text{env}}) & \text{in } (0, T) \times \mathbb{R}^d \\
v(T, x) = g(x)
\end{cases}
\]

where \( \nu := \sigma^2/2 \), \( \Delta := \Delta_x \), \( \nabla := \nabla_x \), and \( H \) is the Hamiltonian associated to \( L \):

\[ H(p) := \sup_{\alpha \in \mathbb{R}^d} \{ p \cdot \alpha - L(\alpha) \} \]

Moreover the feedback control

\[ \hat{\alpha}(t, x) = -\nabla H(\nabla v(t, x)) \]

is optimal.
The optimal process
\[ d\hat{X}_t = -\nabla H(\nabla \nu(\hat{X}_t))dt + \sigma dW_t \]
has a distribution whose density \( m \) solves the
Kolmogorov-Fokker-Plank equation
\[
\begin{aligned}
\frac{\partial m}{\partial t} - \nu \Delta m + \text{div}(m \nabla H(\nabla \nu)) &= 0 & \text{in } (0, T) \times \mathbb{R}^d \\
m(0, x) &= m_o(x)
\end{aligned}
\]
where \( m_o \geq 0, \int_{\mathbb{R}^d} m_o(x)dx = 1, \)
is the distribution of the initial position of the system.
The PDEs for value and density of the optimal process are

\[
\begin{align*}
-\frac{\partial v}{\partial t} - \nu \Delta v + H(\nabla v) &= F(x, m_{env}) \quad \text{in} \ (0, T) \times \mathbb{R}^d \\
\frac{\partial m}{\partial t} - \nu \Delta m + \text{div}(m \nabla H(\nabla v)) &= 0 \quad \text{in} \ (0, T) \times \mathbb{R}^d \\
v(T, x) &= g(x) , \quad m(0, x) = m_o(x)
\end{align*}
\]

and \( m_{env} \rightarrow v, \ v \rightarrow m \) are well-defined maps.

If \( m_{env} \rightarrow v \rightarrow m \) has a fixed point, i.e. \( m = m_{env} \), then \( m \) is an equilibrium distribution of the agents, each behaving optimally as long as the population distribution remains the same.
The PDEs for value and density of the optimal process are

\[
\begin{align*}
-\frac{\partial v}{\partial t} - \nu \Delta v + H(\nabla v) &= F(x, m_{env}) \quad \text{in } (0, T) \times \mathbb{R}^d \\
\frac{\partial m}{\partial t} - \nu \Delta m + \text{div}(m \nabla H(\nabla v)) &= 0 \quad \text{in } (0, T) \times \mathbb{R}^d \\
v(T, x) &= g(x), \quad m(0, x) = m_o(x),
\end{align*}
\]

and \( m_{env} \mapsto v, \ v \mapsto m \) are well-defined maps.

If \( m_{env} \mapsto v \mapsto m \) has a fixed point, i.e. \( m = m_{env} \),

then \( m \) is an equilibrium distribution of the agents,

each behaving optimally as long as the population distribution remains the same.
We have heuristically derived the basic system of 2 evolutive PDEs of MFGs

(MFE)

\[
\begin{aligned}
-\frac{\partial v}{\partial t} - \nu \Delta v + H(\nabla v) &= F(x, m) \quad \text{in } (0, T) \times \mathbb{R}^d \\
\frac{\partial m}{\partial t} - \nu \Delta m + \text{div}(m \nabla H(\nabla v)) &= 0 \quad \text{in } (0, T) \times \mathbb{R}^d \\
v(T, x) &= g(x), \quad m(0, x) = m_0(x),
\end{aligned}
\]

Data: \(\nu, H, F, m_0, g\); Unknows: \(m(t, x) = \text{equilibrium distribution of the agents at time } t; v(t, x) = \text{value function of the representative agent}\)

1st equation is backward parabolic H-J-B with a possibly non-local cost term \(F(x, m)\),

2nd equation is forward parabolic K-F-P equation, linear in \(m\).

3rd line: terminal and initial conditions.
Well-posedness?

Existence was proved by Lasry and Lions under various sets of assumptions (mostly for periodic data). A simple example [P. Cardaliaguet, Notes 2010] is

- $H(p) = |p|^2$
- $g, F$ bounded and Lipschitz (w.r.t. Kantorovitch-Rubinstein distance of prob measures)
- $m_o$ Hölder, $\int_{\mathbb{R}^d} |x|^2 m_o(x) dx < +\infty$.

Uniqueness is not expected in general, true for $H$ convex under the monotonicity condition (as in the static game)

$$\int_{\mathbb{R}^d} [F(x, m_1) - F(x, m_2)] d(m_1 - m_2)(x) > 0, \quad \forall m_1 \neq m_2,$$

which means crowd aversion.
Existence was proved by Lasry and Lions under various sets of assumptions (mostly for periodic data).
A simple example [P. Cardaliaguet, Notes 2010] is
- $H(p) = |p|^2$
- $g, F$ bounded and Lipschitz (w.r.t. Kantorovitch-Rubinstein distance of prob measures)
- $m_0$ Hölder, $\int_{\mathbb{R}^d} |x|^2 m_0(x) dx < +\infty$.

Uniqueness is not expected in general, true for $H$ convex under the monotonicity condition (as in the static game)

$$\int_{\mathbb{R}^d} [F(x, m_1) - F(x, m_2)] d(m_1 - m_2)(x) > 0, \quad \forall m_1 \neq m_2,$$

which means crowd aversion.
MFG with long-time-average cost

For the same control system

\[ dX_s = \alpha_s ds + \sigma dW_s, \quad X_0 = x \in \mathbb{R}^d \]

take the long-time-average (or "ergodic") cost functional:

\[ J(x, \alpha.) := \liminf_{T \to +\infty} \frac{1}{T} E \left[ \int_0^T L(\alpha_t) + F(X_t, m) \, dt \right], \]

Assume the dynamics is on the torus \( \mathbb{T}^d \), i.e., \( F(\cdot, m) \) is \( \mathbb{Z}^d \)-periodic, so all admissible controls produce an ergodic diffusion process \( X_s \).

Now the Hamilton-Jacobi-Bellman equation is

\[ -\nu \Delta v + H(\nabla v) + \lambda = F(x, m) \quad \text{in} \quad \mathbb{R}^d \]

If it has a solution pair \( \lambda, v(\cdot) \), then the value and the optimal control are

\[ \lambda = \inf_{\alpha.} J(x, \alpha.) = J(x, \hat{\alpha}), \quad \hat{\alpha}(x) = -\nabla H(\nabla v(x)) \]
Mean Field Games PDEs: stationary

The MFG PDEs now are elliptic, with an additive eigenvalue

\[
\begin{aligned}
-\nu \Delta v + H(\nabla v) + \lambda &= F(x, m) \quad \text{in } \mathbb{T}^d, \\
\nu \Delta m + \text{div}(\nabla H(\nabla v) m) &= 0 \quad \text{in } \mathbb{T}^d, \\
\int_{\mathbb{T}^d} m(x) dx &= 1, \quad m > 0,
\end{aligned}
\]

Data: \( \nu, H, F \); 
Unknowns:

\( m(x) \) = equilibrium distribution of the agents = invariant measure of the optimal process; 
\( \lambda \) = value 
\( v(x) \), such that \( \nabla H(\nabla v) \) = optimal feedback.
Microscopic justification?

Main mathematical question: how are these systems of PDEs related to Nash equilibria of \( N \)-person differential games, with large \( N \)?

The state of the \( i \)-th player is

\[
dX^i_s = \alpha^i_s ds + \sigma dW^i_s, \quad X^i_s = x^i \in \mathbb{R}^d, \quad i = 1, \ldots, N
\]

\( W^i_s \) independent Brownian motions, \( \alpha^i_s \) = control of \( i \)-th player,

long-time-average cost functional of the \( i \)-th player:

\[
J^i_T(t, x^1, \ldots, x^N, \alpha^1, \ldots, \alpha^N) := E \left[ \int_t^T L(\alpha^i_s) + F \left( X^i_s, \frac{\sum_{k \neq i} \delta X^k_s}{N - 1} \right) ds \right],
\]

depending on the players \( k \neq i \) only via their empirical measure

\[
\frac{1}{N-1} \sum_{k \neq i} \delta X^k_s
\]

\( \delta_x \) is the Dirac mass at \( x \).
Nash equilibrium feedbacks for $N$ players

Such equilibria can be synthesised by solving a system of $N$ parabolic HJB PDEs in $Nd$ dimensions for the value functions $v_i$, $i = 1, ..., N$, nonlinear and strongly coupled.

There is large theory on existence of solutions, mostly by Bensoussan and Frehse (’80s - now).

Question: in what sense are they "close to" solutions of the MFG system of PDEs as $N \to \infty$?

This is very hard in general and was largely open until this year, with some (interesting) partial answers.

Given a solution $(v, m)$ of the evolutive MFG system of PDEs (MFE) the candidate optimal feedback is 

$$\hat{\alpha}(t, x) := -\nabla H(\nabla v(t, x)).$$

Assume all the players use this feedback: $\tilde{\alpha}_s^i := \hat{\alpha}(s, X_s^i)$.

Then $\forall \varepsilon > 0 \exists N_\varepsilon$ such that $\forall N \geq N_\varepsilon, \forall i = 1, \ldots, N, \forall$ admissible $\alpha_i$,

$$J_i^T(t, x^1, \ldots, x^N, \tilde{\alpha}^1, \ldots, \tilde{\alpha}^N) \leq J_i^T(t, x^1, \ldots, x^N, \hat{\alpha}^1, \ldots, \alpha_i, \ldots, \tilde{\alpha}^N) + \varepsilon$$
On the large population limit 2: ergodic costs

2. For the long-time-average cost functional \( J \) the system of PDEs producing the Nash equilibrium feedback can be simplified to

\[
\begin{aligned}
-\nu \Delta v_i + H(\nabla v_i) + \lambda_i &= \int_{\mathbb{T}^d} F \left( x, \frac{\sum_{k \neq i} \delta_{x^k}}{N-1} \right) \prod_{k \neq i} dm_k(x^k), \\
\nu \Delta m_i + \text{div} (\nabla H(\nabla v_i) m_i) &= 0, \quad \text{in } \mathbb{T}^d, \quad i = 1, \ldots, N, \\
\int_{\mathbb{T}^d} m_i(x) dx &= 1, \quad m_i > 0,
\end{aligned}
\]

weakly coupled and in dimension \( d \) (instead of \( Nd! \)).

**Theorem [Lasry-Lions ’06]**

(i) the system has a solution \( \lambda_i^N, v_i^N, m_i^N, i = 1, \ldots, N \) and for any solution \( (\lambda_i^N, v_i^N, m_i^N)_{i,N} \) is relatively compact in \( \mathbb{R} \times C^2(\mathbb{T}^d) \times W^{1,p}(\mathbb{T}^d) \),

(ii) fixed \( i \), the lim of any converging subsequence as \( N \to \infty \) solves (MFS)
3. Linear-Quadratic MFG with ergodic cost [M.B. - F. Priuli 2014]:

\[ dX_i^t = (AX_i^t - \alpha_i^t)dt + \sigma dW_i^t, \quad X_0^i = x^i \in \mathbb{R}^d, \quad i = 1, \ldots, N \]

running cost = quadratic form in \( \alpha_i^t \) and \( X_i^t \):

the system of \( 2N \) PDEs for \( N \)-person Nash equilibria can be solved by matrix Riccati equations,

the solution \( v_i^N \) are quadratic and \( m_i^N \) are Gaussian,

they converge as \( N \to \infty \) to a solution of (MFE).

4. Probabilistic approach to MFG [M. Fischer ’14, D. Lacker ’14]:

convergence of Nash equilibria for \( N \)-person game with finite horizon to an equilibrium of MFG by weak convergence methods, without PDEs.
On the large population limit: the main result

Convergence of solutions of the system of $N$ HJB PDEs for the finite horizon problem to a solution of the evolutive MFG system of PDEs (MFE):

Problem si related to propagation of chaos in statistical phisics.

Covers also the case of common noise, i.e., the noises $W^i_s$ are NOT independent.

Main tool: the master equation, a fully nonlinear PDE in infinite dimensions.
In the 70s the economist Thomas Schelling made some simple simulations to understand the formation of segregated neighbourhoods in US cities.

Blue people and red people live in a chessboard. Each individual is happy if the percentage of same-color individuals among his neighbors is above a given threshold $a$. If he’s not happy, he moves to another free house.

Schelling’s experiments

30% similar wanted, 15% unhappy initially (x)
converges quickly to 0 unhappy and 75% similar in average! Islands form: segregation.
... and with some noise

\( a = 35\%, \ 85\% \) similar in the end:

\( a = 70\%, \ 96\% \) similar in the end, but it keeps oscillating:
Schelling’s conclusions

"The interplay of individual choices, where unorganized segregation is concerned, is a complex system with collective results that bear no close relation to the individual intent"

I.o.w., even in this oversimplified model, knowing individuals’ intent does not allow you to foresee the social outcome, and knowing the social outcome does not give you an accurate picture of individuals’ intent.

There are several videos on YouTube showing experiments of Schelling’s neighbourhoods, and various free software is available online to make such experiments.

This model is considered as a prototype of the modern field of artificial societies.

Schelling also got the Nobel Prize in Economics in 2005 with R. Aumann,
"for having enhanced our understanding of conflict and cooperation through game-theory analysis".
Cost functionals for $N + N$-person games

Want to build differential games and MFG with cost functionals reproducing Schelling’s ideas and see the qualitative properties of solutions, e.g., if segregation occurs.

Cost for the $i$-th player of the 1st population:
for $0 < a_j < 1$, $a_j = \%$ similar wanted by population $j$

$$F_{i}^{1,N}(x_1, \ldots, x_N, y_1, \ldots, y_N) = \left( \frac{\#\{x_k \in U(x_i) : k \neq i\}}{\#\{x_k \in U(x_i) : k \neq i\} + \#\{y_k \in U(x_i)\}} - a_1 \right)^{-},$$

Cost for the $i$-th player of the 2nd population:

$$F_{i}^{2,N}(x_1, \ldots, x_N, y_1, \ldots, y_N) = \left( \frac{\#\{y_k \in U(y_i) : k \neq i\}}{\#\{y_k \in U(y_i) : k \neq i\} + \#\{x_k \in U(y_i)\}} - a_2 \right)^{-}.$$
Can also be written as

$$F_{i}^{1, N}(x_{1}, \ldots, x_{N}, y_{1}, \ldots, y_{N}) = F^{1, N}(x_{i}, \frac{1}{N-1} \sum_{i \neq k} \delta_{x_{k}}, \frac{1}{N} \sum \delta_{y_{k}})$$

$$F^{1, N}(x_{i}, m_{1}, m_{2}) := \left( \frac{\int_{U(x_{i})} m_{1}}{\int_{U(x_{i})} m_{1} + \frac{N}{N-1} \int_{U(x_{i})} m_{2}} - a_{1} \right)^{-} ,$$

$$F_{i}^{2, N}(x_{1}, \ldots, x_{N}, y_{1}, \ldots, y_{N}) = F^{2, N}(y_{i}, \frac{1}{N} \sum_{i \neq k} \delta_{x_{k}}, \frac{1}{N-1} \sum \delta_{y_{k}})$$

$$F^{2, N}(y_{i}, m_{1}, m_{2}) := \left( \frac{\int_{U(y_{i})} m_{2}}{\int_{U(y_{i})} m_{2} + \frac{N}{N-1} \int_{U(y_{i})} m_{1}} - a_{2} \right)^{-} .$$
Regularized cost functionals

\[ F^{1,N}(x, m_1, m_2) := \left( \frac{\int_{\Omega} K(x - y)dm_1(y)}{\int_{\Omega} K(x - y)dm_1(y) + \frac{N}{N-1} \int_{\Omega} K(x - y)dm_2(y) + \eta_1} - a_1 \right)^- \],

where \( K \) is a regularizing kernel with support in \( B(0, \rho) \), \( \eta_1 > 0 \);

\[ F^{2,N}(x, m_1, m_2) := \left( \frac{\int_{\Omega} K(x - y)dm_2(y)}{\int_{\Omega} K(x - y)dm_2(y) + \frac{N}{N-1} \int_{\Omega} K(x - y)dm_1(y) + \eta_2} - a_2 \right)^- \],

\( \eta_2 > 0 \). They are continuous on \( \mathcal{P}(\Omega) \times \mathcal{P}(\Omega) \) and tend to an obvious limit \( F^i \) as \( N \to \infty \), since \( \frac{N}{N-1} \to 1 \).
MFG PDEs for two populations: stationary

For two populations with ergodic costs the stationary equations are

\[
\begin{align*}
-\nu \Delta v_i + H_i(x, \nabla v_i) + \lambda_i &= F_i(x, m_1, m_2), \quad i = 1, 2, \\
-\nu \Delta m_i - \text{div}(m_i \nabla \rho H_i(x, \nabla v_i)) &= 0,
\end{align*}
\]

(MFGs)

1. **Periodic boundary conditions:**
   - existence of solutions and estimates [M.B. - E. Feleqi 2014]
   - convergence of $N + N$ system of HJB-KFP equations to a solution of (MFGs) [Feleqi 2013]

2. **Neumann boundary conditions:**

\[
\begin{align*}
\partial_n v_i &= 0, \quad \text{on } \partial \Omega, \\
\nu \partial_n m_i + m_i \nabla \rho H_i(x, \nabla v_i) \cdot n &= 0, \quad i = 1, 2.
\end{align*}
\]

- existence of solutions and estimates [M. Cirant 2015]
Evolutive MFG with Neumann boundary conditions

\[
\begin{aligned}
-\partial_t v_i - \nu \Delta v_i + H^i(x, \nabla v_i) &= F^i(x, m_1, m_2) \quad \text{in } \Omega \times [0, T] \\
\partial_t m_i - \nu \Delta m_i &= \text{div}(\nabla_p H^i(x, m_i \nabla v_i)), \quad i = 1, 2, \\
\partial_n v_i(x) &= 0, \quad \text{on } \partial\Omega, \\
\nu \partial_n m_i(x, t) + m_i D_p H^i(x, Dv_i(x, t)) \cdot n(x) &= 0, \\
v_i(x, T) &= g(x), \quad m_i(x, 0) = m_{i,0}(x), \quad i = 1, 2.
\end{aligned}
\]

Theorem [Y. Achdou - M.B. - M. Cirant]

Assume $H^i$ satisfy $D_p H^i(x, p) \cdot p \geq -C(1 + |p|^2)$, $F^i$ takes value in a bounded set of $W^{1,\infty}(\overline{\Omega})$, $g \in W^{1,\infty}(\overline{\Omega})$, $m_{i,0} \in C^{2,\beta}(\overline{\Omega})$ + compatibility conditions at $\partial\Omega$.

Then (MFGe) has a classical solution.
Evolutive MFG with Neumann boundary conditions

\[
\begin{aligned}
-\partial_t v_i - \nu \Delta v_i + H^i(x, \nabla v_i) &= F^i(x, m_1, m_2) \quad \text{in } \Omega \times [0, T] \\
\partial_t m_i - \nu \Delta m_i &= \text{div}(\nabla_p H^i(x, m_i \nabla v_i)), \quad i = 1, 2, \\
\partial_n v_i(x) &= 0, \quad \text{on } \partial \Omega, \\
\nu \partial_n m_i(x, t) + m_i D_p H^i(x, Dv_i(x, t)) \cdot n(x) &= 0, \\
v_i(x, T) &= g(x), \quad m_i(x, 0) = m_{i,0}(x), \quad i = 1, 2.
\end{aligned}
\]

\textbf{Theorem [Y. Achdou - M.B. - M. Cirant]}

Assume $H^i$ satisfy $D_p H^i(x, p) \cdot p \geq -C(1 + |p|^2)$,
$F^i$ takes value in a bounded set of $W^{1,\infty}(\Omega)$, $g \in W^{1,\infty}(\Omega)$,
$m_{i,0} \in C^{2,\beta}(\overline{\Omega})$ + compatibility conditions at $\partial \Omega$.

Then (MFGGe) has a classical solution.
Qualitative properties: segregation?

The simplest example: no noise \( \nu = 0 \), \( d = 1 \) and \( H^i(x, \rho) = |\rho|^2 \). Then (MFGs) becomes

\[
\begin{align*}
\frac{(v'_k)^2}{2} + \lambda_k &= F^k(x, m_1, m_2) \quad \text{in } (c, d), \\
(v'_k m_k)' &= 0, \quad k = 1, 2,
\end{align*}
\]

Neumann B.C. in viscosity sense at \( c, d \).

Explicit multiple solutions, if

– the threshold is below xenophobia: \( a_k < 0.5 \), \( k = 1, 2 \),
– the size \( \rho \) of the neighbourhood \( \mathcal{U}(x) \) is not large,
– \( F^k \) is constant if both \( m_k \) are constant:

1. uniform distribution: \( m_k = \frac{1}{d-c} \), \( v_k = 0 \), \( \lambda_k = F^k(x, m_1, m_2) \), \( k = 1, 2 \)
2. segregated solution (\( m_1 \) and \( m_2 \) have disjoint support):

\[
m_1(x) = \frac{1}{x_2 - x_1} \chi_{[x_1,x_2]}(x), \quad m_2(x) = \frac{1}{x_4 - x_3} \chi_{[x_3,x_4]}(x)
\]

for any choice \( c = x_0 < x_1 < \ldots < x_4 < x_5 = d \) with \( x_{i+1} - x_i > \rho \).
Qualitative properties: segregation?

The simplest example: no noise $\nu = 0$, $d = 1$ and $H^i(x, p) = |p|^2$. Then (MFGs) becomes

$$\begin{cases}
\frac{(v'_k)^2}{2} + \lambda_k = F^k(x, m_1, m_2) \quad \text{in} \ (c, d), \\
(v'_k m_k)' = 0, \quad k = 1, 2,
\end{cases}$$

Neumann B.C. in viscosity sense at $c, d$.

Explicit multiple solutions, if
– the threshold is below xenophobia: $a_k < 0.5$, $k = 1, 2$,
– the size $\rho$ of the neighbourhood $\mathcal{U}(x)$ is not large,
– $F^k$ is constant if both $m_k$ are constant:

1. uniform distribution: $m_k = \frac{1}{d-c}$, $v_k = 0$, $\lambda_k = F^k(x, m_1, m_2)$, $k = 1, 2$

2. segregated solution ($m_1$ and $m_2$ have disjoint support):

$$m_1(x) = \frac{1}{x_2 - x_1} \chi_{[x_1, x_2]}(x), \quad m_2(x) = \frac{1}{x_4 - x_3} \chi_{[x_3, x_4]}(x)$$

for any choice $c = x_0 < x_1 < \ldots < x_4 < x_5 = d$ with $x_{j+1} - x_j > \rho$. 

Segregation in a simplified problem

Each $V^k$ is local and linear:

\[
\begin{aligned}
-\nu v_1'' + \frac{(v_1')^2}{2} + \lambda_1 &= m_2 & \text{in } (c, d), \\
-\nu v_2'' + \frac{(v_2')^2}{2} + \lambda_2 &= m_1 \\
-\nu m_k'' + (v_k' m_k)' &= 0, & k = 1, 2, \\
v_k'(c) = v_k'(d) = m_k'(c) = m_k'(d) &= 0.
\end{aligned}
\]

Theorem (Cirant JMPA 2015)

If $0 < \nu < \nu_0$ then (SS) has at least two different solutions, and the non-constant solution satisfies

\[\int_{\Omega} m_1 m_2 \leq C\nu^2.\]

This says that there is segregation in the vanishing viscosity limit. Similar results hold also in higher space dimension for "variational" systems.
Segregation in a simplified problem

Each $V^k$ is local and linear:

$$\begin{cases}
-\nu v_1'' + \frac{(v_1')^2}{2} + \lambda_1 = m_2 & \text{in } (c, d), \\
-\nu v_2'' + \frac{(v_2')^2}{2} + \lambda_2 = m_1 \\
-\nu m_k'' + (v_k' m_k)' = 0, & k = 1, 2, \\
v_k'(c) = v_k'(d) = m_k'(c) = m_k'(d) = 0.
\end{cases}$$

Theorem (Cirant JMPA 2015)

If $0 < \nu < \nu_0$ then (SS) has at least two different solutions, and the non-constant solution satisfies $$\int_\Omega m_1 m_2 \leq C \nu^2.$$ This says that there is segregation in the vanishing viscosity limit. Similar results hold also in higher space dimension for "variational" systems.
Numerical methods: stationary case [A. - B. - C.]

The system (MFGs) with the eigenvalues $\lambda_i$ has no standard approximation.

A natural approximation would be via the (MFGe) with large $T$ (by Cardaliaguet, Lasry, Lions, Porretta), but this is very heavy form the computationally point of view.

We consider a finite difference version of the forward-forward system

\[
\begin{aligned}
&\partial_t v_i - \nu_i \Delta v_i + H^i(x, Dv_i) = V^i[m_1, m_2], & \Omega \times (0, T) \\
&\partial_t m_i - \nu_i \Delta m_i - \text{div}(D_p H^i(x, Dv_i)m_i) = 0, & \Omega \times (0, T) \\
&\partial_n v_i = 0, \partial_n m_i + m_i D_p H^i(x, Dv_i) \cdot n = 0 & \partial \Omega \times (0, T) \\
&v_i = 0, m_i = m^0 & \Omega \times \{0\},
\end{aligned}
\]

for a large number of iterations (large $T$).

Motivated by the ergodic theory for HJB equations, we expect that for the numerical time-derivatives $\partial_t u_i \rightarrow \text{constant} =: \lambda_i$ we are approximating a solution of the stationary system (MFGs).
1D simulations

There is always convergence for large number of time-steps. If $\nu$ is large, convergence to constant $m_1, m_2$. Here $\nu = .05$, $a = 0.4$ (NOT xenophobic), and we see the segregation.

Solutions with many peaks are not detected by this method. Same qualitative behavior for $a = 0.7$. 
Numerical methods: evolutive case

How to deal with the **backward-forward** time structure?

Define the operator \( m_i \mapsto \mu_i \), by solving discrete versions of HJB, KFP

\[
\begin{aligned}
-\partial_t v_i - \nu \Delta v_i + H^i(x, v_i) &= F^i(x, m_1, m_2), \quad \text{in } \Omega \times [0, T], \\
\partial_t \mu_i - \nu \Delta \mu_i - \text{div}(D_p H^i(x, Dv_i) \mu_i) &= 0,
\end{aligned}
\]

Neumann B.C.,

\[
\begin{aligned}
v(x, T) &= v_T(x), \\
\mu_i(x, 0) &= m_{i,0}(x), \quad i = 1, 2.
\end{aligned}
\]

Find an approximate **FIXED POINT** \( m_i \) via a Newton’s method.

- Positivity of \( m_i \) is preserved; any \( \nu \geq 0.01 \) is ok.
- Initial guess \( m^0(x, t) \) for fixed point of \( m_i \mapsto \mu_i \) is extremely important.

The experiments are done (for simplicity) with localized cost functionals \( F^i \) (depend only on \( m_k(x) \)) and with a term that penalises overcrowding.
$a = 0.4$

$\nu = 0.15$: large noise $\Rightarrow$ uniform distribution

$\nu = 0.05$: small noise $\Rightarrow$ segregation
\[ a = 0.4 \]
\[ \nu = 0.05 \]

\( \nu = 0.05 \), different initial guess in Newton’s method \( \Rightarrow \) different numerical solution!
Large threshold: oscillations

\[ a = 0.7: \text{xenophobic populations, same behavior as } a = 0.4 \text{ for some time...} \]

but then the populations move in the opposite direction..... and later they keep oscillating: see the movie!
Large threshold: oscillations

\[ a = 0.7: \text{xenophobic populations,} \]
\[ \text{same behavior as } a = 0.4 \text{ for some time...} \]

\[ \text{but then the populations move in the opposite direction...} \]
\[ \text{and later they keep oscillating: see the movie!} \]
Large threshold: oscillations

\[ a = 0.7: \] xenophobic populations, same behavior as \( a = 0.4 \) for some time....

but then the populations move in the opposite direction..... and later they keep oscillating: see the movie!
Low threshold of happiness, i.e., not-xenophobic populations: segregation
Higher threshold of happiness, i.e., xenophobic populations: oscillations
Some conclusions

- MFG is a young theory with many challenging open problems;
- there are many potential applications, most yet to be found, especially to economics and social sciences;
- MFG with several interacting populations is at a very early stage and much can be done, e.g., proving rigorously qualitatively properties in segregation or aggregation models.
