Sweeping processes were proposed and thoroughly studied by **J.J. Moreau** in the seventies, As a partial viewpoint, consider a time-moving closed convex set $C(t)$ which drags a point $u(t)$, so this point must stay in $C(t)$ at every time t , and the opposite of its velocity, say $-\frac{du}{dt}(t)$, has to be normal to the set $C(t)$.

To take into account the nonsmoothness of the boundary of the convex set $C(t)$, the law of motion is formulated as

$$\begin{cases} \frac{du}{dt}(t) \in -N_{C(t)}(u(t)), a.e. t \in [0, T] \\ u(0) = u_0 \in C(0) \\ u(t) \in C(t) \quad \forall t \in [0, T], \end{cases} \quad (1)$$

where $N_{C(t)}(\cdot)$ denotes the normal cone operator of the convex set $C(t)$ in the sense of convex analysis in a Hilbert space H .

Existence and uniqueness of solutions of such systems and their classical variants :

- ▷ subjected to perturbation forces,
- ▷ non convex prox-regular sets C ,
- ▷ state dependent set $C(t, x)$
- ▷ second-order sweeping processes ...

have been considered by many authors in the literature.

The purpose of the present talk is to study a Cauchy problem

$$\dot{x}(t) \in F(x(t)) - N_C(x(t)), \quad F(x) \subset \partial g(x), \quad x(0) = x_0 \in C, \quad (3)$$

- ▷ in a infinite dimensional Hilbert space H ,
- ▷ the closed set C is locally prox-regular at x_0 (hence N_C is hypomonotone set valued mapping),
- ▷ the set valued mapping F is **not necessarily the whole subdifferential** of g , and we **take the plus sign**, instead of the classical minus.
- ▷ The system (3) can be considered as a **non convex cyclical monotone differential inclusion** under **control term** $u(t) \in -N_C(\cdot)$ which guarantees that the trajectory $x(t)$ always belongs to the desired set C for all $t \in [0, T]$.
We prove **(local) existence** of solutions.

In [Castaing, C., Syam, '03],
the authors proved the existence of solutions of problem (3),

$$\dot{x}(t) \in F(x(t)) - N_C(x(t)), \quad F(x) \subset \partial g(x), \quad x(0) = x_0 \in C,$$

In [Castaing, C., Syam, '03],
the authors proved the existence of solutions of problem (3),

$$\dot{x}(t) \in F(x(t)) - N_C(x(t)), \quad F(x) \subset \partial g(x), \quad x(0) = x_0 \in C,$$

- the closed set C was supposed to be **compact and uniformly r-prox-regular**,

It is also worth mentioning that problem (3) in the more general form

$$\begin{aligned} \dot{x}(t) &\in F(x(t)) - \partial V(x(t)), \\ F(x) &\subset \partial g(x), \quad x(0) = x_0 \in \text{dom} V, \end{aligned} \quad (4)$$

- g is φ -convex of order two
 - V has a φ -monotone subdifferential of order two (shortly $V \in MS(2)$)
- has been studied by : [Cardinali, T., Colombo, G., Papalini, F., Tosques, M., Nonlinear'97]

It is also worth mentioning that problem (3) in the more general form

$$\begin{aligned} \dot{x}(t) &\in F(x(t)) - \partial V(x(t)), \\ F(x) &\subset \partial g(x), \quad x(0) = x_0 \in \text{dom} V, \end{aligned} \quad (4)$$

- g is φ -convex of order two
- V has a φ -monotone subdifferential of order two (shortly $V \in MS(2)$)

has been studied by : [Cardinali, T., Colombo, G., Papalini, F., Tosques, M., Nonlinear'97]

Notice that we can obtain (3) from (4), by taking $V = \delta_C$, the indicator function of the set C , i.e. $\delta_C(x) = 0$ for $x \in C$ and $\delta_C(x) = \infty$ for $x \in H \setminus C$.

It is also worth mentioning that problem (3) in the more general form

$$\begin{aligned} \dot{x}(t) &\in F(x(t)) - \partial V(x(t)), \\ F(x) &\subset \partial g(x), \quad x(0) = x_0 \in \text{dom} V, \end{aligned} \quad (4)$$

- g is φ -convex of order two
- V has a φ -monotone subdifferential of order two (shortly $V \in MS(2)$)

has been studied by : [Cardinali, T., Colombo, G., Papalini, F., Tosques, M., Nonlinear'97]

Notice that we can obtain (3) from (4), by taking $V = \delta_C$, the indicator function of the set C , i.e. $\delta_C(x) = 0$ for $x \in C$ and $\delta_C(x) = \infty$ for $x \in H \setminus C$.

Indeed, as C is locally prox-regular, then $V = \delta_C$ is pln (proposition 3.3 in [M.Mazade ad L.Thibault, '12) and so $MS(2)$.

Despite the similarity of (3) and (4), **the problems are quite different**, since in general with $V = \delta_C$ the level set $\{x \in H; V(x) \leq r\}$ is **not compact**, and **these were basic assumption** in previous works.

Despite the similarity of (3) and (4), **the problems are quite different**, since in general with $V = \delta_C$ the level set $\{x \in H; V(x) \leq r\}$ is **not compact**, and **these were basic assumption** in previous works.

Since these condition **do not holds** for (3), *she has to be replaced by suitable substitute in case of sweeping processes.*

Despite the similarity of (3) and (4), **the problems are quite different**, since in general with $V = \delta_C$ the level set $\{x \in H; V(x) \leq r\}$ is **not compact**, and **these were basic assumption** in previous works.

Since these condition **do not holds** for (3), *she has to be replaced by suitable substitute in case of sweeping processes.*

In this talk, we give a new approach, in which **the compactness assumption is shifted** from the set C to the set-valued map F .

- While one would like to consider very general sets C there are limits to possible sets on which the existence of solutions (well-posedness) of sweeping processes

$$\dot{x}(t) \in F(x(t)) - N_C(x(t)), \quad F(x) \subset \partial g(x), \quad x(0) = x_0 \in C,$$

can be developed.

- Namely, For a fixed closed subset C , the set-valued map $x \longrightarrow N_C(x)$ is not upper semicontinuous which is needed for the proof of existence of solutions.

Uniformly r -prox-regular set

- We say that C is **uniformly r -prox-regular** provided the inequality

$$\langle v, y - x \rangle \leq \frac{1}{2} r \|y - x\|^2$$

holds $\forall x, y \in C, \forall v$ the unit external normal to C .

Uniformly r -prox-regular set

- We say that C is **uniformly r -prox-regular** provided the inequality

$$\langle v, y - x \rangle \leq \frac{1}{2} r \|y - x\|^2$$

holds $\forall x, y \in C$, $\forall v$ the unit external normal to C .

- an **external tangent ball** with radius smaller than $\frac{1}{2}r$ depending on the tangency point x , can be rolled around C with it's closure **touching C only at x** .

- In particular uniformly r -prox-regular sets **can have outside corners and outside cusps, but not inside corners.**

locally prox-regular set

Definition

For positive real numbers r and α , the closed set C is said to be (r, α) **prox-regular** at a point $\bar{x} \in C$ provided that for any $x \in C \cap B(\bar{x}, \alpha)$ and any $v \in N_C^P(x)$ such that $\|v\| \leq r$, one has

$$x = \text{proj}_C(x + v).$$

The set C is said to be **r -uniformly prox-regular** when $\alpha = +\infty$.

primal lower nice function

Let us now define **primal lower nice function in a quantified** way [Mazade and Thibault '12].

Definition

Let $f : H \rightarrow \mathbb{R} \cup \{+\infty\}$ be a proper lower semicontinuous function. The function f is said to be primal lower nice (pln, for short) on an open convex set \mathcal{O} with $\mathcal{O} \cap \text{dom}f \neq \emptyset$ if there exists some real number $c \geq 0$ such that for all $x \in \mathcal{O} \cap \text{dom}\partial^p f(x)$ and for all $v \in \partial^p f(x)$ one has

$$f(y) \geq f(x) + \langle v, y - x \rangle - c(1 + \|v\|)\|y - x\|^2, \quad (5)$$

for each $y \in \mathcal{O}$.

The real $c \geq 0$ will be called a pln constant for f over \mathcal{O} and we will say that **f is c -pln** on \mathcal{O} .

We have the following existence and uniqueness result [Mazade and Thibault '12].

Let C be an (r, α) -prox-regular set at the point $x_0 \in C$ and let any real number $\eta_0 \in]0, \alpha[$. Then for any

$\bar{x} \in B(x_0, \alpha - \eta_0) \cap C$, any positive real number $\tau \leq T_0 - T$, and any mapping $h \in L^1([0, T], H)$ such that

$\int_{T_0}^{T_0+\tau} \|h(s)\| ds < \eta_0/2$, the differential variational inequality

$$\dot{x}(t) \in -N_C(x(t)) + h(t), \quad x(0) = \bar{x}, \text{ a.e. } t \in [T_0, T_0 + \tau], \quad (6)$$

has an absolutely continuous solution

$x : [T_0, T_0 + \tau] \rightarrow B(\bar{x}, \eta_0) \cap C$. Moreover, $\|\dot{x}(t)\| \leq$
 $\|\dot{x}(t) - h(t)\| + \|h(t)\| \leq 2\|h(t)\| \quad \text{a.e. } t \in [T_0, T_0 + \tau]$.

and

$$\|(\dot{x}_k^n)(t)\| \leq 2M, \text{ a.e. } t \in [t_k^n, t_{k+1}^n]$$

sequence of approximates solutions

Define $x_n(\cdot), f_n(\cdot) : [0, \bar{T}] \rightarrow H$ by

$$x_n(t) = \sum_{k=0}^{n-1} x_k^n(t) \chi_{[t_k^n, t_{k+1}^n]}(t), \quad f_n(t) = \sum_{k=0}^{n-1} f_k^n(t) \chi_{(t_k^n, t_{k+1}^n]}(t)$$

where χ_A is the characteristic function of the set A .

The mapping $x_n(\cdot)$ is absolutely continuous on $[0, \bar{T}]$ with

$$x_n(t) \in B(x_0, \eta_0) \cap C; \quad \forall t \in [0, \bar{T}] \quad (8)$$

Further, putting

$$\theta_n(t) := t_k^n \quad \text{if } t \in [t_k^n, t_{k+1}^n[\quad \text{for } k \in 0, \dots, n-1, \quad \theta_n(\bar{T}) = \bar{T} \quad (9)$$

we have

$$\dot{x}_n(t) \in -N_C(x_n(t)) + f_n(t), \quad x_n(0) = x_0, \quad \text{a.e. } t \in [0, \bar{T}] \quad (10)$$

Convergence of sequences

Let us define $Z_n(t) := \int_0^t f_n(s) ds$.

Then for all $t \in [0, \overline{T}]$ the set $\{Z_n(t), n \in N^*\}$ is contained in the strong compact set $\overline{T} \overline{\text{co}}(\{0\} \cup \mathcal{K})$ and so it is **relatively strongly compact** in H .

Fix $m, n \in N^*$.

Put $\varepsilon_{m,n} := \|Z_m - Z_n\|_\infty \rightarrow 0$, and $w_n(t) := x_n(t) - Z_n(t)$, we obtain

$$\frac{d}{dt}(\|w_m(t) - w_n(t)\|^2) \leq \frac{2M}{r} \|w_n(t) - w_m(t)\|^2 + \gamma \varepsilon_{m,n},$$

where γ is some positive constant independent of m, n and t . As $\|w_m(0) - w_n(0)\| = 0$, the **Gronwall inequality** implies for almost t

$$\|w_m(t) - w_n(t)\|^2 \leq L \varepsilon_{m,n},$$

L is some positive constant independent of m, n and t . Hence $(w_n)_n$ converges uniformly to some mapping w and so $(x_n)_n$ **converges uniformly** to some mapping $x := w + Z$.

We prove that

$$\dot{x}(t) \in -N_C(x(t)) + f(t), \quad a.e \quad t \in [0, \bar{T}]$$

By construction we have

$$-\dot{x}_n(t) + f_n(t) \in N_C(x_n(t)) \cap \bar{B}(0, M) = M\partial d_C(x_n(t)).$$

Since $(-\dot{x}_n + f_n)_n$ converges weakly in $L^2([0, \bar{T}], H)$ and $(x_n)_n$ converges strongly in $C([0, \bar{T}], H)$

By invoking a closure type Lemma

We prove that

$$\dot{x}(t) \in -N_C(x(t)) + f(t), \quad a.e \quad t \in [0, \bar{T}]$$

By construction we have

$$-\dot{x}_n(t) + f_n(t) \in N_C(x_n(t)) \cap \bar{B}(0, M) = M\partial d_C(x_n(t)).$$

Since $(-\dot{x}_n + f_n)_n$ converges weakly in $L^2([0, \bar{T}], H)$ and $(x_n)_n$ converges strongly in $C([0, \bar{T}], H)$

By invoking a closure type Lemma

$$-\dot{x}(t) + f(t) \in M\partial^C d_C(x(t)), \quad a.e \quad t \in [0, \bar{T}]. \quad (11)$$

The last inclusion and $x(t) \in C$ ensure

$$\begin{cases} \dot{x}(t) \in -N_C(x(t)) + f(t), & a.e \quad t \in [0, \bar{T}] \\ x(t) \in B(x_0, \eta_0) \cap C; & \forall t \in [0, \bar{T}] \\ x(0) = x_0 \in C, \end{cases} \quad (12)$$

Convergence for the norm topology of L^2_H of the sequence $(\dot{x}_n(\cdot))$

- By exploiting that g is $c - pln$,

- Integrating

$$\langle \dot{x}(t), \dot{x}(t) \rangle = \langle f(t), \dot{x}(t) \rangle. \text{ and } \langle \dot{x}_n(t), \dot{x}_n(t) \rangle = \langle f_n(t), \dot{x}_n(t) \rangle.$$

we obtain

$$\limsup_n \int_0^{\bar{T}} \|\dot{x}_n(t)\|^2 dt \leq \int_0^{\bar{T}} \|\dot{x}(t)\|^2 dt.$$

By the weak lower semicontinuity of the norm, we deduce that

$$\lim_n \int_0^{\bar{T}} \|\dot{x}_n(t)\|^2 dt = \int_0^{\bar{T}} \|\dot{x}(t)\|^2 dt,$$

which implies that $(\dot{x}_n)_n$ converges to \dot{x} in the **strong topology** $L^2([0, \bar{T}], H)$.

Therefore, there exists a subsequence, still denoted by $(\dot{x}_n)_n$ which converges pointwise a.e. to \dot{x} .

$$\dot{x}(t) \in -N_C(x(t)) + F(x(t)), \quad a.e \quad t \in [0, \bar{T}].$$

Define the set-valued mapping $G(x) := -M\partial d_C(x)$, $x \in H$.

Fix $t \in [0, \bar{T}] \setminus \mathcal{N}$, we have $(d^*(A, B) := \sup\{d(a, B) : a \in A\}$
for $A, B \subset H$)

$$\begin{aligned} d(\dot{x}_n(t), G(x(t)) + F(x(t))) &\leq d^*(G(x_n(t)) + F(x_n(\theta_n(t))), G(x(t)) + \\ &\leq d^*(G(x_n(t)), G(x(t))) + d^*(F(x_n(\theta_n(t))), F(x(t))). \end{aligned}$$

Since $\dot{x}_n(t) \rightarrow \dot{x}(t)$, $x_n(t) \rightarrow x(t)$ and $\dot{x}_n(\theta_n(t)) \rightarrow \dot{x}(t)$
strongly in H , the upper semicontinuity of F and G give

$$d(\dot{x}(t), G(x(t)) + F(x(t))) = 0.$$

As $x(t) \in C$ we finally get

$$\begin{aligned}\dot{x}(t) \in G(x(t)) + F(x(t)) &= -M\partial^p d_C(x(t)) + F(x(t)) \\ &\subset -N_C(x(t)) + F(x(t)).\end{aligned}$$

This completes the proof of Theorem. ■

▷ In this talk, the compactness assumption is shifted from the set C to the perturbation F . More precisely, we cannot use Arzela-Ascolis theorem .

However we prove that (x_n) is a Cauchy sequence in the space $C([0, T], H)$. These arguments, used with convex-valued mapping F and uniformly prox-regular set C (see [Bounkhel and Thibault '05]), still hold for (3).

▷ The property

$$\langle \dot{x}(t), \dot{x}(t) \rangle = \langle f(t), \dot{x}(t) \rangle \quad a.e \quad t$$

guarantees the convergence for the norm topology of L^2_H of the sequence $(\dot{x}_n(\cdot))$.
