Ada 2005 code patterns for provable real-time programming

Task model summary – 1

- Static set of tasks
  - Ada: all tasks at library level
- Tasks issue jobs repeatedly
  - Task cycle: activation, execution, suspension
    - Single activation point, no blocking
- Real-time attributes
  - Activation
    - Periodic or cyclic: every T time units
    - Sporadic: at least T time units between consecutive events
  - Execution
    - Worst case execution time (WCET) assumed to be known
    - Deadline: D time units after activation

Task model summary – 2

- Task communication
  - Shared variables with mutually exclusive access
    - Ada: protected objects with procedures and functions
  - No conditional synchronization
    - Except for sporadic task activation
    - Ada: PO with a single entry
- Scheduling model
  - Fixed-priority pre-emptive
    - Ada: FIFO within priorities
- Access protocol for shared objects
  - Immediate priority ceiling
    - Ada: Ceiling_Locking policy

Profile definition

- The profile is enforced by means of a configuration pragma

```
pragma Profile (Ravenscar);
```

which is equivalent to a set of Ada restrictions and three additional configuration pragmas:

```
pragma Task_Dispatching_Policy (FIFO_Within_Priorities);
pragma Locking_Policy (Ceiling_Locking);
pragma Detect_Blocking;
```

Ravenscar restrictions

```
No_Abort_Statements,
No_Dynamic_Attachment,
No_Dynamic_Priorities,
No_Implicit_Heap_Allocations,
No_Local_Protected_Objects,
No_Local_Timing_Events,
No_Protected_Type_Allocators,
No_Relative_Delay,
No_Requeue_Statements,
No_Select_Statements,
No_Specific_Termination_Handlers,
No_Task_Allocators,
No_Task_Hierarchy,
No_Task_Termination,
Simple_Barriers,
Max_Entry_Queue_Length => 1,
Max_Protected_Entries => 1,
Max_Task_Entries => 0,
No_Dependence => Ada.Asynchronous_Task_Control,
No_Dependence => Ada.Calendar,
No_Dependence => Ada.Execution_Time.Group_Budget,
No_Dependence => Ada.Execution_Time.Timers,
No_Dependence => Ada.Task_Attributes
```

Restriction checking

- Almost all of the restrictions can be checked at compile time
- A few restrictions can only be checked at run time
  - Potentially blocking operations in protected operation bodies
  - Priority ceiling violation
  - More than one call queued on a protected entry or a suspension object
  - Task termination

Potentially blocking operations

- Potentially blocking operations
  - Protected entry call statement
  - Delay until statement
  - Call on a subprogram whose body contains a potentially blocking operation
- Pragma Detect_Blocking requires detection of potentially blocking operations
  - Exception Program_Error must be raised if detected at run-time
  - Blocking need not be detected if it occurs in the domain of a foreign language (e.g. C)

Other run-time checks

- Priority ceiling violation
- More than one call waiting on a protected entry or a suspension object
  - Program_Error must be raised in both cases
- Task termination
  - Program behaviour must be documented
  - Possible effects include
    - Silent termination
    - Holding the task in a pre-terminated state
    - Execution on an application-defined termination handler
      - Use of the new Ada.Task_Termination package (C.7.3)

Other restrictions

- Some restrictions on the sequential part of the language may be useful in conjunction with the Ravenscar profile
  - No_Dispatch
  - No_IO
  - No_Recursion
  - No_Unchecked_Access
  - No_Allocators
  - No_Local_Allocators
- See **ISO/IEC TR 15942**, *Guide for the use of the Ada Programming Language in High Integrity Systems* for the details

Execution-time measurement

- The CPU time consumed by tasks can be monitored
- Per-task CPU clocks can be defined
  - Set at 0 before task activation
  - The clock value increases as the task executes

Ada.Execution_Time

```
with Ada.Task_Identification;
with Ada.Real_Time; use Ada.Real_Time;
package Ada.Execution_Time is
   type CPU_Time is private;
   CPU_Time_First : constant CPU_Time;
   CPU_Time_Last  : constant CPU_Time;
   CPU_Time_Unit  : constant := implementation-defined-real-number;
   CPU_Tick       : constant Time_Span;
   function Clock
     (T : Ada.Task_Identification.Task_Id
          := Ada.Task_Identification.Current_Task)
     return CPU_Time;
   ...
end Ada.Execution_Time;
```

Execution-time timers

- A user-defined event can be fired when a CPU clock reaches a specified value
  - An event handler is automatically invoked by the runtime
  - The handler is an (access to) a protected procedure
- Basic mechanism for execution-time monitoring

Ada.Execution_Time.Timers

```
with System;
package Ada.Execution_Time.Timers is
   type Timer (T : not null access constant
                    Ada.Task_Identification.Task_Id) is
      tagged limited private;
   type Timer_Handler is
      access protected procedure (TM : in out Timer);
   Min_Handler_Ceiling : constant System.Any_Priority
      := implementation-defined;
   procedure Set_Handler (TM      : in out Timer;
                          In_Time : in Time_Span;
                          Handler : in Timer_Handler);
   procedure Set_Handler (TM      : in out Timer;
                          At_Time : in CPU_Time;
                          Handler : in Timer_Handler);
   ...
end Ada.Execution_Time.Timers;
```

Group budgets

- Groups of tasks with a global execution-time budget can be defined
  - Basic mechanism for server-based scheduling
  - Can be used to provide temporal isolation among groups of tasks

Group budgets (spec)

```
with System;
package Ada.Execution_Time.Group_Budgets is
   type Group_Budget is tagged limited private;
   type Group_Budget_Handler is
      access protected procedure (GB : in out Group_Budget);
   ...
   Min_Handler_Ceiling : constant System.Any_Priority
      := implementation-defined;
   procedure Add_Task (GB : in out Group_Budget;
                       T  : in Ada.Task_Identification.Task_Id);
   ...
   procedure Replenish (GB : in out Group_Budget;
                        To : in Time_Span);
   procedure Add (GB       : in out Group_Budget;
                  Interval : in Time_Span);
   ...
   procedure Set_Handler (GB      : in out Group_Budget;
                          Handler : in Group_Budget_Handler);
   ...
end Ada.Execution_Time.Group_Budgets;
```

Timing events

- Lightweight mechanism for defining code to be executed at a specified time
  - Does not require an application-level task
  - Analogous to interrupt handling
- The code is defined as an event handler
  - An (access to) a protected procedure
  - Directly invoked by the runtime

Ada.Real_Time.Timing events

```
package Ada.Real_Time.Timing_Events is
   type Timing_Event is tagged limited private;
   type Timing_Event_Handler is
      access protected procedure (Event : in out Timing_Event);
   procedure Set_Handler (Event   : in out Timing_Event;
                          At_Time : in Time;
                          Handler : in Timing_Event_Handler);
   ...
   procedure Cancel_Handler (Event     : in out Timing_Event;
                             Cancelled : out Boolean);
   ...
end Ada.Real_Time.Timing_Events;
```

Scheduling and dispatching policies

- Additional dispatching policies
  - Non preemptive
    - Run-to-completion semantics (per partition)
    - Built-in support provided
  - Round robin
    - Within specified priority band
    - Built-in support provided
    - Dispatch on quantum expiry is deferred until end of protected action
  - Earliest Deadline First
    - Within specified priority band
    - Built-in support provided for relative and absolute "deadline"
    - EDF ordered ready queues
    - Guaranteed form of resource locking (preemption level + deadline)

Priority-band dispatching

- Mixed policies can coexist within a single partition
  - Priority specific dispatching policy can be set by configuration
  - Protected objects can be used for tasks to communicate across different policies
  - Tasks do not move across bands

An object-oriented approach

- Real-time components are objects
  - Instances of classes
  - Internal state + interfaces
  - Based on a reduced set of archetypes
   - Cyclic & sporadic tasks
    - Protected data
    - Passive data

Two ways to ensure consistent temporal behavior

- Static WCET analysis and response-time analysis can be used to assert correct temporal behavior at design time
- Platform mechanisms can be used at run time to ensure that temporal behavior stays within the asserted boundaries
  - Clocks, timers, timing events, …
- Conveniently complementary approaches

Run-time services

- The execution environment must provide run-time services to preserve properties asserted at model level
  - Real-time clocks & timers
  - Execution-time clocks & timers
  - Predictable scheduling
- We assume an execution environment implementing the Ravenscar model
  - Ada 2005 with the Ravenscar profile
 - Augmented with (restricted) execution-time timers

Component structure
Basic patterns

- Cyclic component
- Sporadic component
- Protected data component
- Passive component

Cyclic component

- Clock-activated activity with fixed rate
- Attributes
  - Period
  - Deadline
  - Worst-case execution time
- The most basic cyclic code pattern does not need the synchronization agent
  - The system clock delivers the activation event
  - The component behavior is fixed and immutable

Cyclic component (basic)
Cyclic thread (spec)

```
task type Cyclic_Thread
   (Thread_Priority : Priority;
    Period          : Positive) is
  pragma Priority(Thread_Priority);
end Cyclic_Thread;
```

(ms)

cannot be Time_Span!

Cyclic thread (body)

```
task body Cyclic_Thread is
  Next_Time : Time := <Start_Time>; -- taken at elaboration time
                                     --+ higher in the system
                                     --+ hierarchy
begin
  loop
    delay until Next_Time; -- so that all tasks start at T0
    OPCS.Cyclic_Operation; -- fixed and parameterless
    Next_Time := Next_Time + Milliseconds(Period);
  end loop;
end Cyclic_Thread;
```

Sporadic component

- Activated by a software-mediated event
  - Signaled by software or hardware interrupts
- Attributes
  - Minimum inter-arrival time
  - Deadline
  - Worst-case execution time
- The synchronization agent of the target component is used to signal the activation event
  - And to store-and-forward signal-related data (if any)

Sporadic component
Sporadic component (spec)

```
task type Sporadic_Thread(Thread_Priority : Priority) is
  pragma Priority(Thread_Priority);
end Sporadic_Thread;

protected type OBCS(Ceiling : Priority) is
  pragma Priority(Ceiling);
  procedure Signal;
  entry    Wait;
private
  Occurred : Boolean := False;
end OBCS;
```

A sporadic thread is activated by calling the Signal *operation*

Sporadic thread (body)

```
task body Sporadic_Thread is
  Next_Time : Time := <Start_Time>;
begin
  delay until Next_Time; -- so that all tasks start at T0
  loop
    OBCS.Wait;
    OPCS.Sporadic_Operation;
    --  may take parameters if they were delivered by Signal
    --+ and retrieved by Wait
  end loop;
end Sporadic_Thread;
```

Sporadic control agent (body)

```
protected body OBCS is
  procedure Signal is
  begin
    Occurred := True;
  end Signal;
  entry Wait when Occurred is
  begin
    Occurred := False;
  end Wait;
end OBCS;
```

Other basic patterns

- **Protected component**
  - No thread, only synchronization and operations
  - Straightforward direct implementation with protected object
- **Passive component**
  - Purely functional behavior, neither thread nor synchronization
  - Straightforward direct implementation with functional package

Temporal properties

- Basic patterns only guarantee periodic or sporadic activation
- They can be augmented to guarantee additional temporal properties at run time
  - Minimum inter-arrival time for sporadic events
  - Deadline for all types of thread
  - WCET budgets for all types of thread

Minimum inter-arrival time

- Violations of the specified separation interval may cause increased interference on lower priority tasks
- Approach: prevent sporadic thread from being activated earlier than stipulated
  - Compute earliest (absolute) allowable activation time
  - Withhold activation (if triggered) until that time

Sporadic thread with minimum separation (spec)

```
task type Sporadic_Thread
   (Thread_Priority : Priority;
    Separation      : Positive) is
  pragma Priority(Thread_Priority);
end Sporadic_Thread;
```

(ms)

*Minimum inter-arrival time
expressed in ms*

Sporadic thread (body)

```
task body Sporadic_Thread is
   Release_Time : Time;
   Next_Release : Time := <Start_Time>;
begin
   loop
      delay until Next_Release;
      OBCS.Wait;
      Release_Time := Clock;
      OPCS.Sporadic_Operation;
      Next_Release := Release_Time + Milliseconds(Separation);
   end loop;
end Sporadic_Thread;
```

Still a single point of activation

Comments

- May incur some temporal drift as the clock is read after task release
  - Hence preemption may hit just after the release but before reading the clock
  - The net effect is a larger separation than required
- It is better to read the clock at the place and time the task is released
  - Within the synchronization agent
    - Which is protected and thus less exposed to general interference

---

Minimum inter-arrival time – alternate pattern

```
task body Sporadic_Thread is
   Release_Time : Time;
   Next_Release : Time := <Start_Time>;
begin
   loop
      delay until Next_Release;
      OBCS.Wait(Release_Time);
      OPCS.Sporadic_Operation;
      Next_Release := Release_Time + Milliseconds(Separation);
   end loop;
end Sporadic_Thread;
```

Recording release time – 1

```
protected type OBCS(Ceiling : Priority) is
   pragma Priority(Ceiling);
   procedure Signal;
   entry Wait(Release_Time : out Time);
private
   Occurred : Boolean := False;
end OBCS;
```

Recording release time – 2

```
protected body OBCS is
   procedure Signal is
   begin
      Occurred := True;
   end Signal;

   entry Wait(Release_Time : out Time) when Occurred is
   begin
      Release_Time := Clock;
      Occurred := False;
   end Wait;
end OBCS;
```

Deadline overruns

- Deadline overruns in a task may occur as a result of
  - Higher priority tasks executing more often than expected
    - Prevented with inter-arrival time enforcement
  - Execution time of the same or higher priority tasks longer than stipulated
    - Programming errors
      - Bounding assertions violated by functional code
    - Inaccurate WCET analysis

Detection of deadline overruns

- Deadline overruns can be detected at run time with the help of timing events
  - A mechanism for requiring some application-level action to be executed at a given time
  - Timing events can only exist at library level under the Ravenscar Profile
    - Statically allocated
- A minor optimization may be possible for periodic tasks
  - Which however breaks the symmetry of patterns

Cyclic thread with deadline overrun detection (spec)

```
task type Cyclic_Thread
   (Thread_Priority : Priority;
    Period          : Positive;
    Deadline        : Positive) is
  pragma Priority(Thread_Priority);
end Cyclic_Thread;
```

(ms)

Thread body

```
Deadline_Overrun : Timing_Event; -- static, local per component
task body Cyclic_Thread is
  Next_Time : Time := <Start_Time>;
  Canceled  : Boolean := False;
begin
  loop
    delay until Next_Time;
    Set_Handler(Deadline_Overrun,
                Next_Time + Milliseconds(Deadline),
                Deadline_Overrun_Handler); -- application-specific
    OPCS.Cyclic_Operation;
    Cancel_Handler(Deadline_Overrun, Canceled);
    Next_Time := Next_Time + Milliseconds(Period);
  end loop;
end Cyclic_Thread;
```

Thread body (streamlined)

```
Deadline_Overrun : Timing_Event; -- static, local per component
task body Cyclic_Thread is
  Next_Time : Time := <Start_Time>;
  Canceled  : Boolean := False;
begin
  loop
    -- setting again cancels any previous event
    Set_Handler(Deadline_Overrun,
                Next_Time + Milliseconds(Deadline),
                Deadline_Overrun_Handler); -- application-specific
    delay until Next_Time;
    OPCS.Cyclic_Operation;
    Next_Time := Next_Time + Milliseconds(Period);
  end loop;
end Cyclic_Thread;
```

Sporadic thread with deadline overrun detection (spec)

```
task type Sporadic_Thread
   (Thread_Priority : Priority;
    Separation      : Positive;
    Deadline        : Positive) is
  pragma Priority(Thread_Priority);
end Sporadic_Thread;
```

(ms)

Thread body

```
Deadline_Overrun : Timing_Event; -- static, local per component
task body Sporadic_Thread is
  Release_Time   : Time;
  Next_Release   : Time := <Start_Time>;
  Cancelled      : Boolean := False;
begin
  loop
    delay until Next_Release;
    OBCS.Wait(Release_Time);
    Set_Handler(Deadline_Overrun,
                Release_Time + Milliseconds(Deadline),
                Deadline_Overrun_Handler); -- application-specific
    OPCS.Sporadic_Operation;
    Cancel_Handler(Deadline_Overrun, Cancelled);
    Next_Release := Release_Time + Milliseconds(Separation);
  end loop;
end Sporadic_Thread;
```

> Can't streamline as the deadline cannot be computed until returning from Wait

Execution-time overruns

- Tasks may execute for longer than stipulated, owing to programming errors
  - Bounding assertions violated by functional code
- WCET values used in temporal analysis may be inaccurate
  - Optimistic vs. pessimistic
- WCET overruns can be detected at run time with the help of execution-time timers
  - Not included in Ravenscar
  - Extended profile

Cyclic thread with WCET overrun detection (spec)

```
task type Cyclic_Thread
   (Thread_Priority : Priority;
    Period          : Positive;
    WCET_Budget     : Positive) is
  pragma Priority(Thread_Priority);
end Cyclic_Thread;
```

(ms)

Thread body

```
task body Cyclic_Thread is
  Next_Time : Time := <Start_Time>;
  Id : aliased constant Task_ID := Current_Task;
  WCET_Timer : Timer(Id'access);
begin
  loop
    delay until Next_Time;
    Set_Handler(WCET_Timer,
                Milliseconds(WCET_Budget),
                WCET_Overrun_Handler); -- application-specific
    OPCS.Cyclic_Operation;
    Next_Time := Next_Time + Milliseconds(Period);
  end loop;
end Cyclic_Thread;
```

Observations

- WCET overruns in sporadic tasks can be detected similarly
  - The timer should be set after the activation
 - There is no need for timer cancellation

Fault handling strategies

- Error logging
  - Only for low-criticality tasks
- Second chance
  - Use slack time and try to complete
- Mode change
  - Switch to *safe mode*
    - *Fail safe* or *fail soft* behaviour

Fault handling scheme

Modifiers

- Cyclic and sporadic objects may have modifier operations
  - Mode change, behavior modifications, etc.
- ATC not allowed in Ravenscar
  - Modifier requests are queued in the OBCS
    - Synchronization agent now required for cyclic components as well
  - The thread takes requests from the queue and executes them whenever possible

---

Cyclic thread with modifier

```
task body Cyclic_Thread is
  Next_Release_Time : Time := <Start_Time>;
  Request : Request_Type;
begin
  loop
    delay until Next_Release_Time;
    OBCS.Get_Request(Request); -- may include operation parameters
    case Request is
      when NO_REQ  => OPCS.Periodic_Activity;
      when ATC_REQ => -- may take parameters
                      OPCS.Modifier_Operation;
    end case;
    Next_Release_Time := Next_Release_Time + Period;
  end loop;
end Cyclic_Thread;
```

Synchronization agent – 1

```
-- for cyclic thread
protected type OBCS (Ceiling: Priority) is
  pragma Priority(Ceiling);
  procedure Put_Request(Request : Request_Type);
  procedure Get_Request(out Request : Request_Type);
private
  Buffer : Request_Buffer; -- bounded queue
end OBCS;
```

Synchronization agent – 2

```
-- for cyclic thread
protected body OBCS(Ceiling : Priority) is
  procedure Put_Request(Request : Request_Type) is
  begin
    Buffer.Put(Request);
  end Put_Request;

  procedure Get_Request(out Request : Request_Type) is
  begin
    if Buffer.Empty then
      Request := NO_REQ;
    else
      Buffer.Get(Request);
    end if;
  end Get_Request;
end OBCS;
```

Ada 2005 compilation chain

- Ada 2005 compiler & linker
  - Full support of Annex D – Real-time systems
- Real-time kernel
  - Implements the Ravenscar tasking model
- Ada run-time system
  - Implements the Ada tasking model on top of the kernel

GNAT for LEON

- Cross-compilation system targeted to LEON2 computers
  - Radiation-hardened SPARC v8
  - ESA standard
- Components
  - GNAT Ada 2005 compiler   (Ada Core)
  - GNARL run-time system   (Ada Core)
 - ORK+ kernel   (UPM)

GNAT compiler

- Ada 2005 cross-compilation system
  - Hosted on GNU/Linux
  - Targeted to ELF-SPARC v8
    - real hardware or simulators
- Current version: GNAT GPL 2007
  - Supports Ada 2005
  - Ported to LEON2 at UPM
   - Including Ravenscar run-time

ORK+

- Lightweight real-time kernel for the Ravenscar tasking model
- Evolution of ORK
  - Developed at UPM under ESA contract
- New Ada 2005 features
  - Timing events
  - Execution-time clocks and timers
 - Group budgets

ORK+ architecture
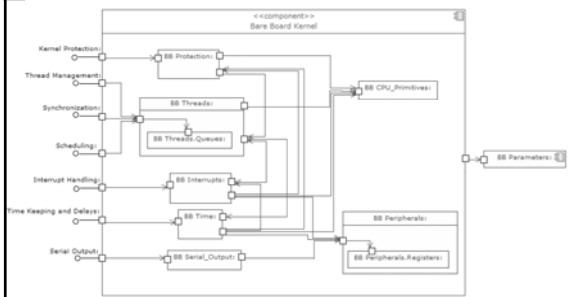

Compilation process

## Cross-compilation and debugging

Running programs

- LEON2 simulator on host platform
  - E.g. TSIM
- LEON2 computer board

Example

```
$ sparc-elf-gnatmake hello
[ $ sparc-elf-gnatmake -g hello -largs -Wl,-Map=hello.map ]
$ tsim –gdb
...
gdb interface: using port 1234
[ on another terminal – local or remote ]
$ sparc-elf-gdb hello
(gdb) target extended-remote 127.0.0.1:1234
...
(gdb) load
...
(gdb) cont
...
(gdb) detach
...
```

GNAT Programming System
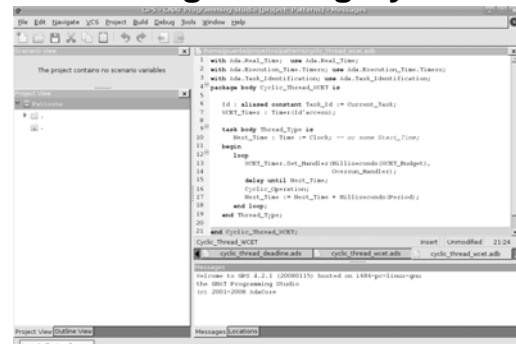

Other tools

- Response time analysis
  - MAST (University of Cantabria, Spain)
- Execution-time (WCET) analysis
  - Bound-T (Tidorum, Finland)
    - Static analysis
  - RapiTime (Rapita Systems, UK)
    - Measurement based
