

3. Scheduling issues

Common approaches /1

■ *Clock-driven (time-driven) scheduling*

- Scheduling decisions are made beforehand (off line) and carried out at predefined time instants
 - The time instants normally occur at regular intervals signaled by a clock interrupt
 - The scheduler first dispatches jobs to execution as due in the current time period and then suspends itself until then next schedule time
 - The scheduler uses an off-line schedule to dispatch
- All parameters that matter must be known in advance
- The schedule is static and cannot be changed at run time
- The run-time overhead incurred in executing the schedule is minimal

Common approaches /2

■ *Weighted round-robin scheduling*

- With basic round-robin
 - All ready jobs are placed in a FIFO queue
 - The job at head of queue is allowed to execute for one time slice
 - If not complete by end of time slice it is placed at the tail of the queue
 - All jobs in the queue are given one time slice in one round
- Weighted correction (as applied to scheduling of network traffic)
 - Jobs are assigned differing amounts of CPU time according a given 'weight' (fractionary) attribute
 - Job J_i gets ω_i time slices per round – one round is $\sum_i \omega_i$ of ready jobs
 - Not good for jobs with precedence relations
 - Response time gets worse than basic RR which is already bad
 - Fit for producer-consumer jobs that operate concurrently in a pipeline

Common approaches /3

■ *Priority-driven (event-driven) scheduling*

- This class of algorithms is *greedy*
 - They never leave available processing resources unutilized
 - They seek local optimization
 - An available resource may stay unused iff there is no job ready to use it
 - A *clairvoyant* alternative may instead defer access to the CPU to incur less contention and thus reduce job response time
 - Anomalies may occur when job parameters change dynamically
- Scheduling decisions are made at run time when changes occur to the "ready queue" and thus on local knowledge
 - The event causing a scheduling decision is called "*dispatching point*"
- It includes algorithms also used in non real-time systems
 - FIFO, LIFO, SETF (shortest e.t. first), LETF (longest e.t. first)
 - Normally applied at every round of RR scheduling

Preemption vs. non preemption

- Can we compare preemptive scheduling with non-preemptive scheduling in terms of performance?
 - There is no response that is valid in general
 - When all jobs have the same release time and the time overhead of preemption is negligible then preemptive scheduling is provably better
 - It would be interesting to know whether the improvement of the last finishing time (a.k.a. *minimum makespan*) under preemptive scheduling pays off the time overhead of preemption
 - For 2 CPU we do know that the minimum makespan for non-preemptive scheduling is never worse than 4/3 of that for preemptive

Further definitions

- Precedence constraints effect release time and deadline
 - One job's release time cannot follow that of a successor job
 - One job's deadline cannot precede that of a predecessor job
- **Effective release time**
 - For a job with predecessors this is the latest value between its own release time and the maximum effective release time of its predecessors plus the WCET of the corresponding job
- **Effective deadline**
 - For a job with successors this is the earliest value between its deadline and the effective deadline of its successors less the WCET of the corresponding job
- For single processor with preemptive scheduling we may disregard precedence constraints and just consider ERT and ED

Optimality /1

- Priorities assigned in accord to (effective) deadlines
 - **Earliest Deadline First** scheduling is *optimal* for single processor systems with independent jobs and preemption
 - For any given job set, EDF produces a feasible schedule if one exists
 - The optimality of EDF falls short under other hypotheses (e.g., no preemption, multicore)

Optimality /2

- Priorities assigned in accord to *slack* (i.e., *laxity*)
 - **Least Laxity First** scheduling is optimal under the same hypotheses as for EDF optimality
 - LLF is far more onerous than EDF to implement as it have to keep tab of execution time!

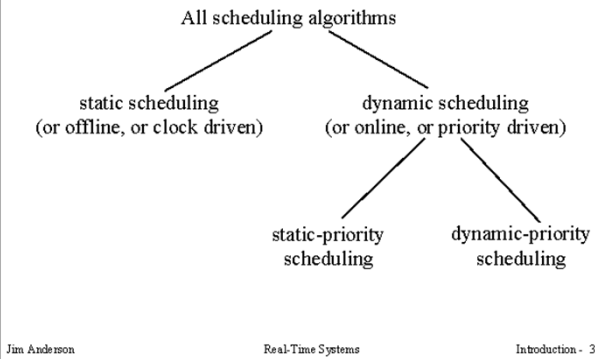

Optimality /3

- If the goal is that jobs just make their deadlines then having jobs complete any earlier has not much point
 - The **Latest Release Time** algorithm follows this logic and schedules jobs backwards from the latest deadline
 - LRT first sets the job with the latest deadline and then the job with the latest release time and so forth
 - A later release time earns a greater deadline
 - LRT does not belong in the priority-driven class as it may defer the execution of a ready job
- Greedy scheduling algorithms may cause jobs to incur larger interference

Predictability of execution

- Initial intuition
 - The execution of job set J under a given scheduling algorithm is **predictable** if the actual start time and the actual response time of every job in J vary within the bounds of the *maximal* and *minimal schedule*
 - *Maximal schedule*: the schedule created by the scheduling algorithm under worst-case assumptions
 - *Minimal schedule*: analogously for best-case
- **Theorem**: the execution of independent jobs with given release time under preemptive priority-driven scheduling on a single processor is predictable

Classification of Scheduling Algorithms

Ramifications for dynamic scheduling

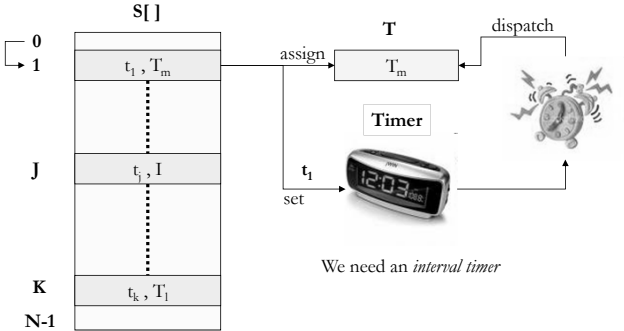

Clock-driven scheduling /1

- **Workload model**
 - N periodic tasks with N constant and statically defined
 - In Jim Anderson’s definition of periodic (not Jane Liu’s)
 - The $(\varphi_i, p_i, e_i, D_i)$ parameters of every task τ_i are constant and statically known
- The schedule is static and committed off line before system start to a table **S** of decision times t_k
 - $S[t_k] = \tau_i$ if a job of task τ_i must be dispatched at time t_k
 - $S[t_k] = I$ (idle) otherwise
 - Schedule computation can be as sophisticated as we like since we pay for it only once and before execution
 - Jobs cannot overrun otherwise the system is in error

Clock-driven scheduling /2

```
Input: stored schedule  $S(t_k)$  for  $k = \{0, \dots, N - 1\}$ ;  $H$  (hyper-period)
SCHEDULER:
   $i = 0$ ;  $k = 0$ ; set timer to expire at  $t_k$  ;
  do forever :
    sleep until timer interrupt;
    if an aperiodic job is executing
      preempt;
    end if;
    current task  $T = S(t_k)$  ;
     $i = i + 1$ ;  $k = i \bmod N$ ;
    set timer to expire at  $[i/N] \times H + t_k$  ; -- at time  $t_k$  in all  $H$  forever
    if current task  $T = I$ 
      execute job at head of aperiodic queue;
    else execute job of task  $T$ ;
    end if;
  end do;
end SCHEDULER
```

Clock-driven scheduling /3

Example

- Static schedule table **S** for **J** would need 17 entries
 - That’s too many and too fragmented!
- **Why 17?**

Clock-driven scheduling /4

- Obvious reasons suggest we should minimize the size and complexity of the cyclic schedule (table S)
 - The scheduling point t_k should occur at regular intervals
 - Each such interval is termed **minor cycle** (*frame*) and has duration f
 - We need a *periodic timer*
 - Within minor cycles there is no preemption but a single minor cycle may contain the execution of multiple jobs
 - φ_i for every task τ_i must be a non-negative integer multiple of f
 - The first job of every task has release time (forcedly) set at the beginning of a minor cycle
- We must therefore enforce some artificial constraints

Clock-driven scheduling /5

- **Constraint 1:** Every job J must complete within f
 - $f \geq \max_{i=\{1..n\}}(e_i)$ so that *overruns* can be detected
- **Constraint 2:** f must be an integer divisor of hyper-period $H : H = Nf$ where N is an integer
 - Satisfied if f is an integer divisor of at least one task period p_i
 - The hyper-period beginning at minor cycle kf for $k = 0, \dots, N - 1$ is termed **major cycle**
- **Constraint 3:** There must be one full frame f between J 's release time t' and deadline $D_j : t' + D_j \geq t + 2f$ so that J can be scheduled in that frame
 - This can be expressed as: $2f - \gcd(p_i, f) \leq D_i$ for every task τ_i

Understanding constraint 3

Example

- $T = \{(0, 4, 1, 4), (0, 5, 2, 5), (0, 20, 2, 20)\}$
 - $H = 20$
 - [c1] : $f \geq \max(e_i) : f \geq 2$
 - [c2] : $\lfloor p_i/f \rfloor - p_i/f = 0 : f = \{2, 4, 5, 10, 20\}$
 - [c3] : $2f - \gcd(p_i, f) \leq D_i : f \leq 2$
- | | |
|--|--|
| $f = 2 : 4 - \gcd(4,2) \leq 4$ OK | $f = 5 : 10 - \gcd(4,2) \leq 4$ KO |
| $4 - \gcd(5,2) \leq 5$ OK | $f = 10 : 20 - \gcd(4,2) \leq 4$ KO |
| $4 - \gcd(20,2) \leq 20$ OK | |
| $f = 4 : 8 - \gcd(4,4) \leq 4$ OK | $f = 20 : 40 - \gcd(4,2) \leq 4$ KO |
| $8 - \gcd(5,4) \leq 5$ KO | |

Clock-driven scheduling /5

- It is very likely that the original parameters of some task set T may prove unable to satisfy all three constraints for any given f simultaneously
- In that case we must decompose T 's jobs by *slicing* their larger e_{max} into fragments small enough to artificially yield a “good” f

Clock-driven scheduling /6

- To construct a cyclic schedule we must therefore make three design decisions
 - Fix an f
 - Slice (the large) jobs
 - Assign (jobs and) slices to minor cycles
- There is a very unfortunate inter-play among these decisions
 - Cyclic scheduling thus is very fragile to any change in system parameters

Clock-driven scheduling /7

```
Input: stored schedule S(k) for k = 0,...,F-1;
CYCLIC_EXECUTIVE:
  t := 0; k := 0;
  do forever:
    sleep until clock interrupt @ time t × f;
    currentBlock = S(k);
    t := t+1; k := t mod F;
    if last job not completed take action;
    end if;
    execute slices in currentBlock;
    while the aperiodic job queue is not empty do
      execute aperiodic job at top of queue;
    end do;
  end do;
end SCHEDULER
```

Example (slicing) – 1/2

$J = \{t_1 = (0, 4, 1, 4), t_2 = (0, 5, 2, 7), t_3 = (0, 20, 5, 20)\}$, $H = 20$
 t_3 causes disruption since we need $e_3 \leq f \leq 4$ to satisfy c_3
 We must therefore slice e_3 : how many slices do we need?

We first look at the schedule with $f=4$ and without t_3 to see what least-disruptive opportunities we have ...

Example (slicing) – 2/2

... then we observe that {1,3,1} is a good choice

$t_3 = \{t_3 = (0, 20, 1, X), t_3 = (0, 20, 3, Y), t_3 = (0, 20, 1, 20)\}$
 $F = (H / f) = 5$
where $X < Y \leq 20$ represent the precedence constraints that must hold between the slices

Real-Time Systems

132 of 390

Design issues /1

- Completing a job much ahead of its deadline is of no use
- If we have spare time we might give aperiodic jobs more opportunity to execute hence make the system more responsive
- The principle of **slack stealing** allows aperiodic jobs to execute in preference to periodic jobs when possible
 - Every minor cycle include some amount of slack time not used for scheduling periodic jobs
 - The slack is a static attribute of each minor cycle
- A scheduler does slack stealing if it assigns the available slack time at the beginning of every minor cycle (instead of at the end)
 - This provision requires a fine-grained interval timer (again!) to signal the end of the slack time for each minor cycle

2012/13 UniPD / T. Vardanega

Real-Time Systems

133 of 390

Design issues /2

- What can we do to handle **overruns**?
 - Halt the job found running at the start of the new minor cycle
 - But that job may not be the one that overrun!
 - Even if it was, stopping it would only serve a useful purpose if producing a late result had no residual *utility*
 - Defer halting until the job has completed all its “critical actions”
 - To avoid the risk that a premature halt may leave the system in an inconsistent state
 - Allow the job some extra time by delaying the start of the next minor cycle
 - Plausible if producing a late result still had *utility*

2012/13 UniPD / T. Vardanega

Real-Time Systems

134 of 390

Design issues /3

- What can we do to handle **mode changes**?
 - A mode change is when the system incurs some reconfiguration of its function and workload parameters
- Two main axes of design decisions
 - With or without deadline during the transition
 - With or without overlap between outgoing and incoming operation modes

2012/13 UniPD / T. Vardanega

Real-Time Systems

135 of 390

Overall evaluation

■ Pro

- Comparatively simple design
- Simple and robust implementation
- Complete and cost-effective verification

■ Con

- Very fragile design
 - Construction of the schedule table is a NP-hard problem
 - High extent of undesirable architectural coupling
- All parameters must be fixed a priori at the start of design
 - Choices may be made arbitrarily to satisfy the constraints on f
 - Totally inapt for sporadic jobs

2012/13 UniPD / T. Vardanega

Real-Time Systems

136 of 390

Priority-driven scheduling

■ Base principle

- Every job is assigned a priority
- The job with the highest priority is selected for execution

■ *Dynamic-priority scheduling*

- Distinct jobs of the same task may have distinct priorities

■ *Static-priority scheduling*

- All jobs of the same task have one and same priority

2012/13 UniPD / T. Vardanega

Real-Time Systems

137 of 390

Dynamic-priority scheduling

■ Two main algorithms

- *Earliest Deadline First* (EDF)
- *Least Laxity First* (LLF)

■ **Theorem** [Liu, Layland: 1973] EDF is optimal for independent jobs with preemption

- Also true with sporadic tasks
- The relative deadline for periodic tasks may be arbitrary with the respect to period ($<$, $=$, $>$)

■ Result trivially applicable to LLF

■ EDF is not optimal for jobs that do not allow preemption

2012/13 UniPD / T. Vardanega

Real-Time Systems

138 of 390

Static (fixed)-priority scheduling (FPS)

■ Two main variants with respect to the strategy for priority assignment

□ *Rate monotonic*

- A task with lower period (faster rate) gets higher priority

□ *Deadline monotonic*

- A task with higher urgency (shorter deadline) gets higher priority

□ What about “*execution-monotonic*”?

■ Before looking at those strategies in more detail we need to fix some basic notions

2012/13 UniPD / T. Vardanega

Real-Time Systems

139 of 390

Dynamic scheduling: comparison criteria /1

- Priority-driven scheduling algorithms that disregard job urgency (deadline) perform poorly
 - The WCET is not a factor of interest for priority!
- How to compare the performance of scheduling algorithms?
- **Schedulable utilization** is a useful criterion
 - An algorithm can produce a feasible schedule for a task set T on a single processor if $U(T)$ does not exceed its schedulable utilization

2012/13 UniPD / T. Vardanega

Real-Time Systems

140 of 390

Dynamic scheduling: comparison criteria /2

- **Theorem** [Liu, Layland: 1973] for single processors the schedulable utilization of EDF is 1
- For arbitrary deadlines, the **density**

$$\delta_k = \frac{e_k}{\min(p_k, D_k)}$$
 is an important feasibility factor
 - $\Delta = \sum_k \delta_k > U$ if $D_i < p_i$ for some τ_i
 - Hence $\Delta \leq 1$ is a sufficient *schedulability test* for EDF

2012/13 UniPD / T. Vardanega

Real-Time Systems

141 of 390

Dynamic scheduling: comparison criteria /3

- The schedulable utilization criterion alone is not sufficient: we must also consider predictability
- On transient overload the behavior of static-priority scheduling can be determined a-priori and is reasonable
 - The overrun of any job of a given task τ does not hinder the tasks with higher priority than τ
- Under transient overload EDF becomes instable
 - A job that missed its deadline is more urgent than a job with a deadline in the future!

2012/13 UniPD / T. Vardanega

Real-Time Systems

142 of 390

Dynamic scheduling: comparison criteria /3

- Other figures of merit for comparison exist
 - **Normalized Mean Response Time** (NMRT)
 - Ratio between the job response time and the CPU time actually consumed for its execution
 - The larger the NMRT value, the larger the task idle time
 - **Guaranteed Ratio** (GR)
 - Number of tasks (jobs) whose execution can be guaranteed versus the total number of tasks that request execution
 - **Bounded Tardiness** (BT)
 - Number of tasks (jobs) whose tardiness can be guaranteed to stay within given bounds

2012/13 UniPD / T. Vardanega

Real-Time Systems

143 of 390

Example (EDF) /1

$$T = \{t_1 = (0, 2, 0.6, 1), t_2 = (0, 5, 2.3, 5)\}$$
$$\text{Density } \Delta(T) = e_1/D_1 + e_2/D_2 = 1.06 > 1$$
$$U(T) = e_1/p_1 + e_2/p_2 = 0.76 < 1$$

What happens to T under EDF?

2012/13 UniPD / T. Vardanega

Real-Time Systems

144 of 390

Example (EDF) /2

$$T = \{t_1 = (0, 2, 1, 2), t_2 = (0, 5, 3, 5)\} \Rightarrow U(t) = \frac{e_1}{p_1} + \frac{e_2}{p_2} = 1.1$$

T has no feasible schedule: what job suffers most under EDF?

$$T = \{t_1 = (0, 2, 0.8, 2), t_2 = (0, 5, 3.5, 5)\} \Rightarrow U(t) = \frac{e_1}{p_1} + \frac{e_2}{p_2} = 1.1$$

T has no feasible schedule: what job suffers most under EDF?

What about

$$T = \{t_1 = (0, 2, 0.8, 2), t_2 = (0, 5, 4, 5)\} \text{ with } U(t) = \frac{e_1}{p_1} + \frac{e_2}{p_2} = 1.2 ?$$

2012/13 UniPD / T. Vardanega

Real-Time Systems

145 of 390

Critical instant /1

- Feasibility and schedulability tests must consider the **worst case** for all tasks
 - The worst case for task τ_i occurs when the worst possible relation holds between its release time and that of all higher-priority tasks
 - The actual case may differ depending on the admissible relation between D_i and p_i
- The notion of **critical instant**-- if one exists -- captures the worst case
 - The response time R_i for a job of task τ_i with release time on the critical instant is the longest possible value for τ_i

2012/13 UniPD / T. Vardanega

Real-Time Systems

146 of 390

Critical instant /2

- Theorem:** under FPS with $D_i \leq p_i \forall i$, the critical instant for task τ_i occurs when the release time of *any* of its jobs is in phase with a job of every higher-priority task in the task set
- Given task τ_i we must find $\max(\omega_{i,j})$ among all its jobs j
$$\omega_{i,j} = e_i + \sum_{(k=1, \dots, i-1)} [(\omega_{i,j} + \varphi_i - \varphi_k)/p_k]e_k - \varphi_i$$

For task indices assigned in decreasing order of priority

 - The summation term in the equation captures the interference that any job j of task τ_i incurs from jobs of all higher-priority tasks $\{\tau_k\}$ between the release time of the first job of task τ_k (with phase φ_k) to the response time of job j of task τ_i , which occurs at $\varphi_i + \omega_{i,j}$

2012/13 UniPD / T. Vardanega

Real-Time Systems

147 of 390

Time-demand analysis /1

- When φ is 0 for all jobs considered then this equation captures the absolute worst case for task τ_i
- This equation stands at the basis of **Time Demand Analysis** which investigates how ω varies as a function of time
 - So long as $\omega(t) \leq t$ for some t within the time interval of interest the supply satisfies the demand, hence the job can complete in time
- **Theorem** [Lehoczky, Sha, Ding: 1989] condition $\omega(t) \leq t$ is an exact feasibility test (necessary and sufficient)
 - The obvious question is for which 't' to check
 - The method proposes to check at all periods of all higher-priority tasks until the deadline of the task under study

2012/13 UniPD / T. Vardanega

Real-Time Systems

148 of 390

Time demand analysis /2

$T = \{t_1 = (-, 3, 1, 3), t_2 = (-, 5, 1.5, 5), t_3 = (-, 7, 1.25, 7)\}$

$U(T) = \sum_i e_i / p_i = 0.82$

phases can be arbitrary since they have no impact on the *critical instant*

This is when the critical-instant job of t_1 completes, where $\omega(t) = t$

$\omega_1(t) \leq t$
hence supply satisfies demand at all t of interest

The supply exceeds the demand

2012/13 UniPD / T. Vardanega

Real-Time Systems

149 of 390

Time demand analysis /3

$T = \{t_1 = (-, 3, 1, 3), t_2 = (-, 5, 1.5, 5), t_3 = (-, 7, 1.25, 7)\}$

$\omega_2(t) \leq t$

The supply exceeds the demand

2012/13 UniPD / T. Vardanega

Real-Time Systems

150 of 390

Time demand analysis /4

$T = \{t_1 = (-, 3, 1, 3), t_2 = (-, 5, 1.5, 5), t_3 = (-, 7, 1.25, 7)\}$

$\omega_3(t) \leq t$

The supply exceeds the demand while it does not at all other t of interest to $t_3(t)$

For $D < p$ it suffices to verify $(\omega(t) \leq t)$ at time instants that are multiple of the period of the highest-priority tasks and $\leq D$

2012/13 UniPD / T. Vardanega

Real-Time Systems

151 of 390

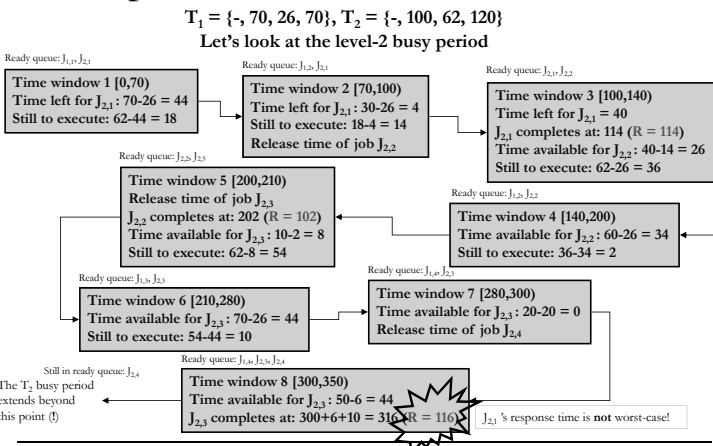

Time demand analysis /5

- It is straightforward to extend TDA to determine the response time of tasks
- The smallest value t that satisfies the fixed-point equation $t = e_i + \sum_{(k=1, \dots, i-1)} \left\lceil \frac{t}{p_k} \right\rceil e_k$ is the *worst-case response time* of task τ_i
- Solutions methods to calculate this value were independently proposed by
 - [Joseph, Pandia: 1986]
 - [Audley, Burns, Richardson, Tindell, Wellings: 1993]

Time demand analysis /6

- What changes in the definition of critical instant when $D > p$?
- **Theorem** [Lehoczky, Sha, Strosnider, Tokuda: 1991] The first job of task τ_i may *not* be the one that incurs the worst-case response time
- Hence we must consider *all* jobs of task τ_i within the so-called **level- i busy period**
 - The (t_0, t) time interval within which the processor is busy executing jobs with priority $\geq i$, release time in (t_0, t) and response time falling within t
 - The release time in (t_0, t) captures the full backlog of interfering jobs
 - The response time of all those jobs falling within t ensures that the busy period includes their completion

Example

Summary

- Initial survey of scheduling approaches
- Important definitions and criteria
- Detail discussion and evaluation of main scheduling algorithms
- Initial considerations on analysis techniques
