CS5412 Spring 2012 (Cloud Computing: Birman)

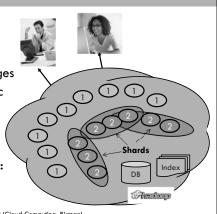

C\$5412: ANATOMY OF A CLOUD

Lecture VII

Ken Birman

Big picture overview

- Client requests are handled in the "first tier" by
 - E.g. PHP or ASP pages And associated logic
- These lightweight services are fast and very nimble
- □ Much use of caching: the second tier

CS5412 Spring 2012 (Cloud Computing: Birman)

How are cloud structured?

- ☐ Clients talk to clouds using web browsers (increasingly more) or the web services standards (increasingly less)
 - But this only gets as far as the outer "skin" of the cloud data center, not the interior
 - Consider Amazon: it can host entire company web sites (like Target.com or Netflix.com), data (AC3), servers (EC2) and even user-provided virtual machines!

CS5412 Spring 2012 (Cloud Computing: Birman)

Many styles of system

- □ Near the edge of the cloud, focus is on vast numbers of clients and rapid response
- □ Inside we find high-volume services that operate in a <u>pipelined</u> manner, <u>asynchronously</u>
- Deep inside the cloud we see a world of <u>virtual</u> <u>computer clusters</u> that are scheduled to share resources and on which applications like MapReduce (Hadoop) are very popular

CS5412 Spring 2012 (Cloud Computing: Birman)

_

In the outer tiers replication is key

- □ We need to replicate
 - <u>Processing</u>: each client has what seems to be a private, dedicated server (for a little while)
 - □ <u>Data</u>: as much as possible, that server has copies of the data it needs to respond to client requests without any delay at all
 - Control information: the entire structure is managed in an agreed-upon way by a decentralized cloud management infrastructure

CS5412 Spring 2012 (Cloud Computing: Birman)

Sharding used in many ways

- The second tier could be any of a number of caching services
 - Memcached: a sharable **in-memory** key-value store
 - Other kinds of Distributed Hash Tables that use key-value APIs
 - Dynamo: A service created by Amazon as a scalable way to represent the shopping cart and similar data
 - BigTable: A very elaborate key-value store created by Google and used not just in tier-two but throughout their "GooglePlex" for sharing information
- □ The notion of sharding is cross-cutting
 - Most of these systems replicate data to some degree

CS5412 Spring 2012 (Cloud Computing: Birman)

What about the "shards"?

- ☐ The caching components running in tier two are central to the responsiveness of tier-one services
 - The basic idea is to always used cached data if at all possible, so the inner services (here, a DB and a search index stored in a set of files) are shielded from "online" load
 - We need to replicate data within our cache to spread loads and provide fault-tolerance
 - But not everything needs to be "fully" replicated. Hence we often use "shards" with just a few replicas

CS5412 Spring 2012 (Cloud Computing: Birman)

Do we always need to shard data?

- □ Imagine a tier-one service running on 100k nodes
 - Can it ever make sense to replicate data on the entire set?
- Yes, if some kinds of information might be so valuable that almost every external request touches it
 - Must think hard about patterns of data access and use
 - Some information needs to be heavily replicated to offer blindingly fast access on vast numbers of nodes
 - The principle is similar to the way Beehive operates
 - Even if we don't make a dynamic decision about the level of replication required, the principle is similar
 - We want the level of replication to match the level of load and the degree to which the data is needed on the critical path

And it isn't just about updates

- ☐ Should also be thinking about patterns that arise when doing reads ("queries")
 - Some can just be performed by a single representative of a service
 - But others might need the parallelism of having several (or even a huge number) of machines do parts of the work concurrently
- ☐ The term sharding is used for data, but here we might talk about "parallel computation on a shard"

CS5412 Spring 2012 (Cloud Computing: Birman)

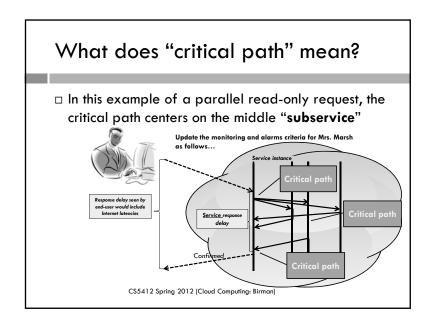

What if a request triggers updates?

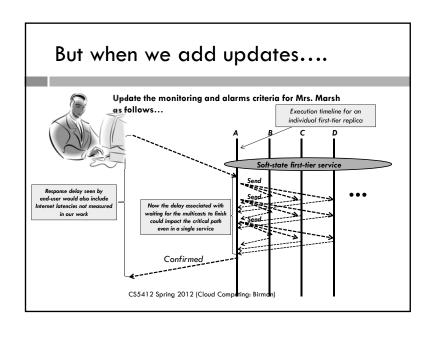

- ☐ If the updates are done **asynchronously** we might not experience much delay on the critical path
 - □ Cloud systems often work this way
 - Avoids waiting for slow services to process the updates but may force the tier-one service to "guess" the outcome
 - For example, could optimistically apply update to value from a cache and just hope this was the right answer
- □ Many cloud systems use these sorts of "tricks" to speed up response time

CS5412 Spring 2012 (Cloud Computing: Birman)

First-tier parallelism

- □ Parallelism is vital to speeding up first-tier services
- □ Key question
 - Request has reached some service instance X
 - Will it be faster...
 - ... For X to just compute the response
 - ... Or for X to subdivide the work by asking subservices to do parts of the job?
- □ Glimpse of an answer
 - Werner Vogels, CTO at Amazon, commented in one talk that many Amazon pages have content from 50 or more parallel subservices that run, in real-time, on your request!

With replicas we just load balance Update the monitoring and alarms criteria for Mrs. Marsh as follows... Response delay seen by end-user would include Internet latencies Confinmed Confirmed Confirmed

What about updating w/o waiting?

- □ Several issues now arise
 - Are all the replicas applying updates in the same order?
 - Might not matter unless the same data item is being changed
 - But then clearly we do need some "agreement" on order
 - What if the leader replies to the end user but then crashes and it turns out that the updates were lost in the network?
 - Data center networks are surprisingly lossy at times
 - Also, bursts of updates can queue up
- □ Such issues result in inconsistency

CS5412 Spring 2012 (Cloud Computing: Birman)

.

Eric Brewer's CAP theorem

- □ In a famous 2000 keynote talk at ACM PODC, Eric Brewer proposed that "you can have just two from Consistency, Availability and Partition Tolerance"
 - He argues that data centers need very snappy response, hence availability is paramount
 - And they should be responsive even if a transient fault makes it hard to reach some service. So they should use cached data to respond faster even if the cached entry can't be validated and might be stale!
- ☐ Conclusion: weaken consistency for faster response

CS5412 Spring 2012 (Cloud Computing: Birman)

(Clarification) Intermission ... /1

- There must be a total order on all operations
 - Logical equivalent to centralization with run-to-completion operation semantics
- Each operation looks as if it were completed at a single instant
- Each update is applied to all relevant replicas at the same logical time
- Consistency that is both instantaneous and global is simply impossible

SCD course @ UNIPD (Tullio Vardanega)

CAP theorem

- ☐ A proof of CAP was later introduced by MIT's Seth Gilbert and Nancy Lynch
 - Suppose a data center service is active in two parts of the country with a wide-area Internet link in between
 - We temporarily cut the link ("partitioning" the network)
 - And present the service with conflicting requests
- ☐ The replicas can't talk to each other so can't sense the conflict
- ☐ If they respond at this point, inconsistency arises

CS5412 Spring 2012 (Cloud Computing: Birman)

(Clarification) Intermission ... /2

□ Availability (A)

- Every request received by a non-failing node must yield a response
- Every request processing must terminate even under severe network failures

□ Partition Tolerance (P)

- Under PT, the network may lose arbitrarily many messages sent from one node to another
- When a network is partitioned, all messages sent from notes in one component of the partition to nodes in another component are lost
- Any node failure can be seen as a network partition

SCD course @ UNIPD (Tullio Vardanega)

_

(Clarification) Intermission ... /3 rise to a network partition) rises exponentially with the number of nodes

 $P(failure) = 1 - P(individual_node_not_failing)^{number_of_nodes}$

□ Choosing C over A in the presence of partitions

■ The system will preserve the guarantees of atomic reads and writes, and reject some requests

□ Choosing A over C

- The system will respond to all requests, potentially returning stale reads and accepting conflicting writes
- Some of the conflicts may be resolved by Lamport's like algorithms

SCD course @ UNIPD (Tullio Vardanega)

Is inconsistency a bad thing?

- ☐ How much consistency is really needed in the first tier of the cloud?
 - Think about YouTube videos: would consistency be an issue here?
 - What about the Amazon "number of units available" counters: will people notice if those are a bit off?
- □ Puzzle: can you come up with a general policy for knowing how much consistency a given thing needs?

CS5412 Spring 2012 (Cloud Computing: Birman)

(Clarification) Intermission ... /4

- □ Brewer's Yield and Harvest notions
- □ Yield
 - The probability of completing a request
 - More useful metric than uptime, as being down at peak or off-peak times generates the same uptime but vastly different yields
- □ Harvest
 - The fraction of data reflected in the response
 - The completeness of the answer to the query data_available total data
- □ System design and implementation can influence whether faults impact Yield, Harvest or both
 - Replicated systems map faults to reduced Yield at peak times
 - Partitioned systems map faults to reduced Harvest for the same Yield

SCD course @ UNIPD (Tullio Vardanega)

CS5412 Spring 2012 (Cloud Computing: Birman

THE WISDOM OF THE SAGES

eBay's Five Commandments

□ As described by Randy Shoup at LADIS 2008

Thou shalt...

- 1. Partition Everything
- 2. Use Asynchrony Everywhere
- 3. Automate Everything
- 4. Remember: Everything Fails
- 5. Embrace Inconsistency

CS5412 Spring 2012 (Cloud Computing: Birman)

James Hamilton's advice

- Key to scalability is decoupling, loosest possible synchronization
- ☐ Any synchronized mechanism is a risk
 - \blacksquare His approach: create a committee
 - Anyone who wants to deploy a highly consistent mechanism needs committee approval

.... They don't meet very often

CS5412 Spring 2012 (Cloud Computing: Birman)

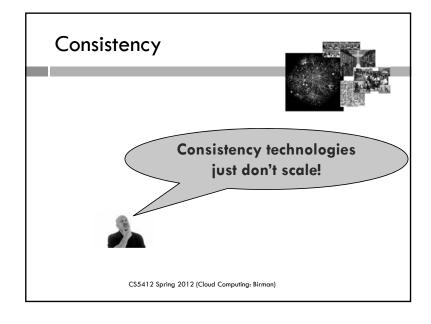

Vogels at the Helm

- $\ \square$ Involved in building a new shopping cart service ...
 - lacktriangle The old one used strong consistency for replicated data
 - New version was build over a DHT, like **Chord**, and has weak consistency with eventual convergence
 - Chord: a scalable P2P lookup service
- $\hfill\Box$ This weakens guarantees ... but
 - □ Speed matters more than correctness

CS5412 Spring 2012 (Cloud Computing: Birman)

_

But inconsistency brings risks too!

My rent check bounced? That can't be right!

- □ Inconsistency causes bugs
 - □ Clients would never be able to trust servers... a free-for-all

- □ Weak or "best effort" consistency?
 - Strong security guarantees demand consistency
 - Would you trust a medical electronic-health records system or a bank that used "weak consistency" for better scalability?

CS5412 Spring 2012 (Cloud Computing: Birman)

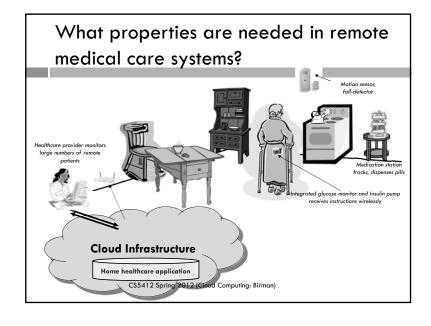

What does "consistency" mean?

- $\hfill \square$ We need to pin this basic issue down!
- □ As used in CAP, consistency is about two things
 - First, that updates to the same data item are applied in some agreed-upon order
 - Second, that once an update is acknowledged to an external user, it won't be forgotten
- □ Not all systems need both properties

CS5412 Spring 2012 (Cloud Computing: Birman)

Puzzle: Is CAP valid in the cloud?

- □ Facts: data center networks don't normally experience partitioning failures
 - Wide-area links do fail
 - But most services are designed to do updates in a single place and mirror read-only data at others
 - So the CAP scenario used in the proof can't arise
- □ Brewer's argument about not waiting for a slow service to respond does make sense
 - Argues for using any single replica you can find
 - But does this preclude that replica being consistent?

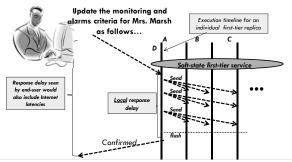

Which matters more: fast response, or durability of the data being updated? Mrs. Marsh has been dizzy. Her stomach is upset and she hasn't been eating well, yet her blood sugars are high Let's stop the oral diabetes medication and increase her insulin, but we'll need to monitor closely for a week Cloud Patient Records DB Need: Strong consistency and durability for data cs5412 Spring 2012 (Cloud Computing: Birman)

Why does monitoring have weaker needs?

- □ When a monitoring system goes "offline" the device turns a red light or something goes on
 - Later, on recovery, the monitoring policy may have changed and a node would need to reload it
 - Moreover, with in-memory replication we may have a strong enough guarantee for most purposes
- ☐ Thus if durability costs enough to slow us down, we might opt for a weaker form of durability in order to gain better scalability and faster responses!

CS5412 Spring 2012 (Cloud Computing: Birman)

What with online monitoring? Update the monitoring and alarms criteria for Mrs. Marsh Execution fineline for an individual found to see the

An online monitoring system might focus on real-time response and value consistency, yet be less concerned with durability

CS5412 Spring 2012 (Cloud Computing: Birman)

This illustrates a challenge!

- Cloud systems just can't be approached in a one-size fits all manner
- □ For performance-intensive scalability scenarios we need to look closely at tradeoffs
 - Cost of stronger guarantee, versus
 - Cost of being faster but offering weaker guarantee
- If systems builders blindly opt for strong properties when not needed, we just incur other costs!
 - Amazon: Each 100ms delay reduces sales by 1%!

Properties we might want

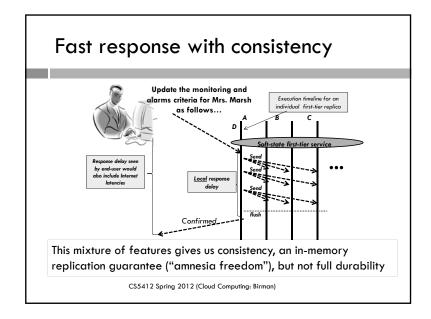

- □ Consistency: Updates in an agreed order
- □ <u>Durability</u>: Once accepted, won't be forgotten
- $\ \square$ Real-time <u>responsiveness</u>: Replies with bounded delay
- Security: Only permit authorized actions by authenticated parties
- □ Privacy: Won't disclose personal data
- □ <u>Resilience</u>: Failures can't prevent the system from providing desired services
- $\ \square$ Coordination: actions won't interfere with one another

CS5412 Spring 2012 (Cloud Computing: Birman)

Does CAP apply deeper in the cloud?

- ☐ The principle of wanting speed and scalability certainly is universal
- ☐ But many cloud services have strong consistency guarantees that we take for granted but depend on
- ☐ Marvin Theimer at Amazon explains
 - Avoid costly guarantees that aren't even needed
 - But sometimes you just need to guarantee something
 - Then, be clever and **engineer it to scale**
 - And expect to revisit it each time you scale out 10x

CS5412 Spring 2012 (Cloud Computing: Birman)

Cloud services and their properties

Service	Properties it guarantees
Memcached	No special guarantees
Google's GFS	File is current if locking is used
BigTable	Shared key-value store with many consistency properties
Dynamo	Amazon's shopping cart: eventual consistency
Databases	Snapshot isolation with log-based mirroring (a fancy form of the ACID guarantees)
MapReduce	Uses a "functional" computing model within which offers very strong guarantees
Zookeeper	Yahoo! file system with sophisticated properties
PNUTS	Yahoo! database system, sharded data, spectrum of consistency options
Chubby	Locking service very strong guarantees
	CS5412 Spring 2012 (Cloud Computing: Birman)

Is there a conclusion to draw?

- $\ \square$ One thing to notice about those services ...
 - Most of them cost 10's or 100's of millions to create!
 - Huge investment required to build strongly consistent and scalable and high performance solutions
 - Oracle's current parallel database: billions invested
- □ CAP isn't about telling Oracle how to build a database product ...
 - CAP is a warning to <u>you</u> that strong properties can easily lead to slow services
 - But thinking in terms of weak properties is often a successful strategy that yields a good solution and requires less effort

CS5412 Spring 2012 (Cloud Computing: Birman)

Core problem?

- □ When can we safely sweep consistency under the rug?
 - If we weaken a property in a safety-critical context, something bad can happen!
 - Amazon and eBay do well with weak guarantees because many applications just didn't need strong guarantees to start with!
 - By embracing their weaker nature, we reduce synchronization and so get better response behavior
- □ But what happens when a wave of high assurance applications starts to transition to cloud-based models?
